# Module 4: Construction

CPSC 310

Reid Holmes & Nick Bradley

# C0

- 285/539 repos have been checked out (53% have started).
- AutoTest latency was < 5 minutes yesterday until 1800.
  - Grew to 75 mins in the late evening.
  - 1200+ jobs on the queue.
- 55+ PROFICIENT solutions.
- 3 AutoTest runs in 24h, instead of 2 for rest of project.
- Deadline 1800 this Friday.

# Project journal

- Details about the first project journal have been posted online.
- Each deliverable will have a journal component.
- This is intended for meta-reflection.
  - Mostly individual, but there will be some team components.
- Two components:
  - Reflect on some specific aspects of past checkpoint.
  - Perform some specific planning tasks for next checkpoint.
- Due exactly 7 days after each project checkpoint.
- Oral discussion with TA the lab after journal submission.

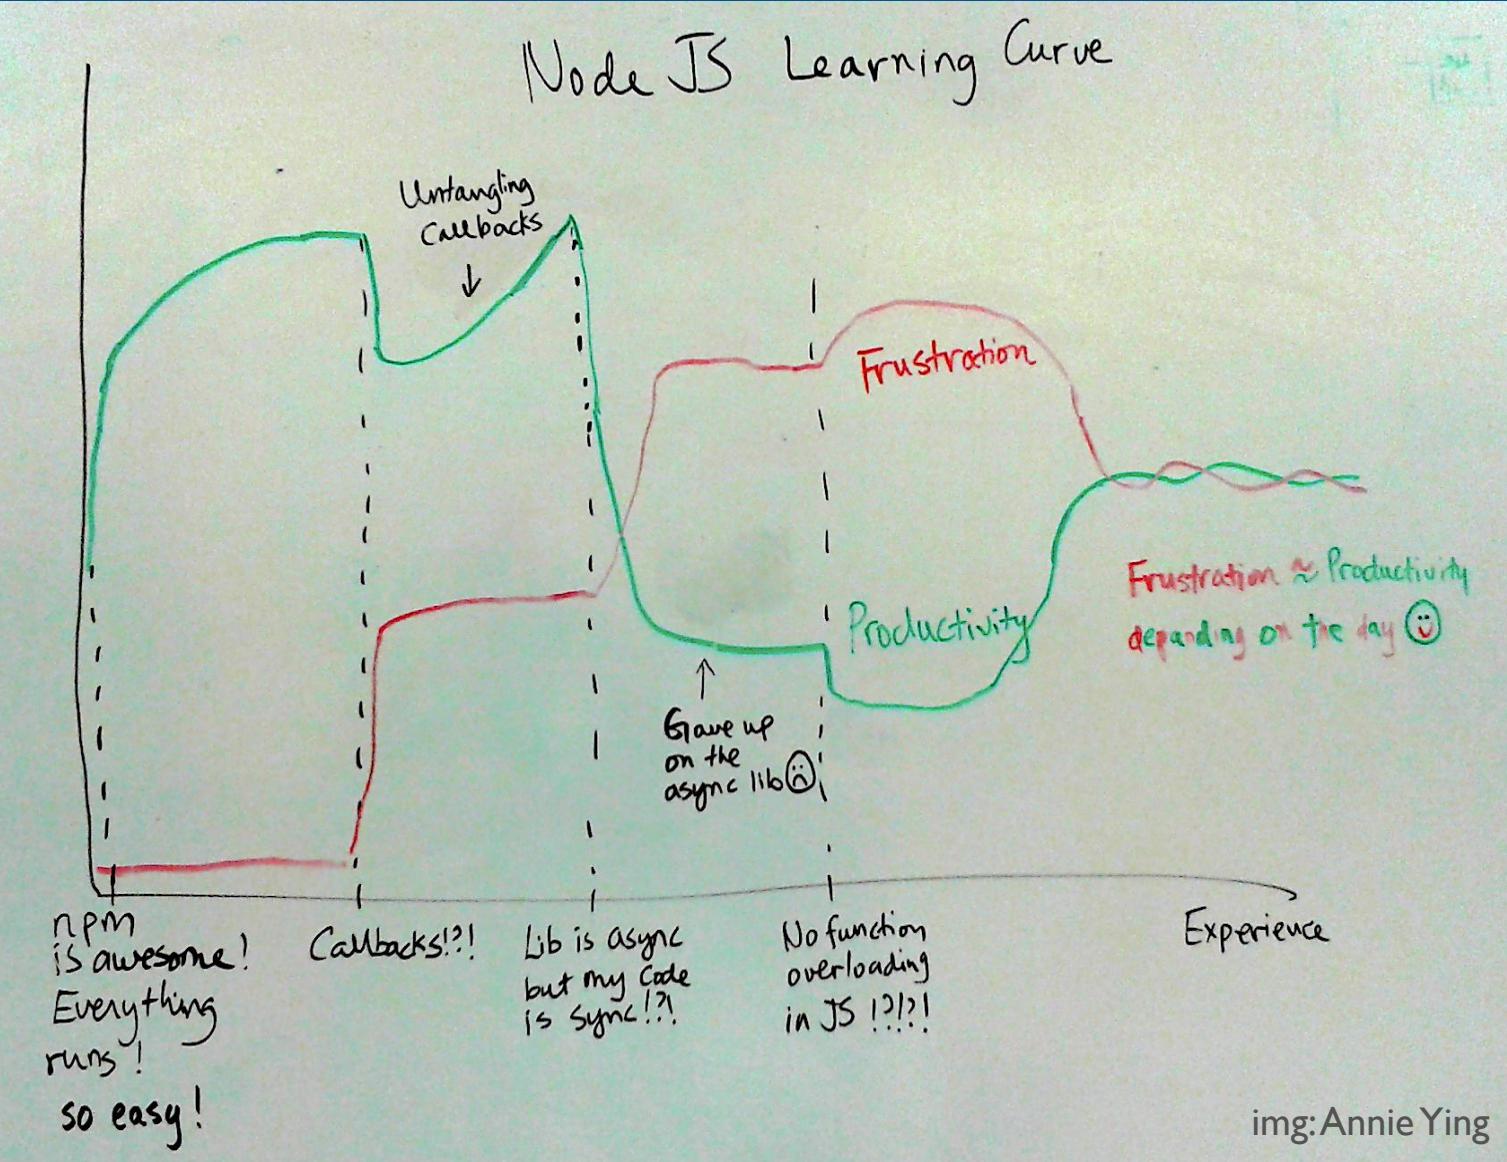

# Examinable skills:

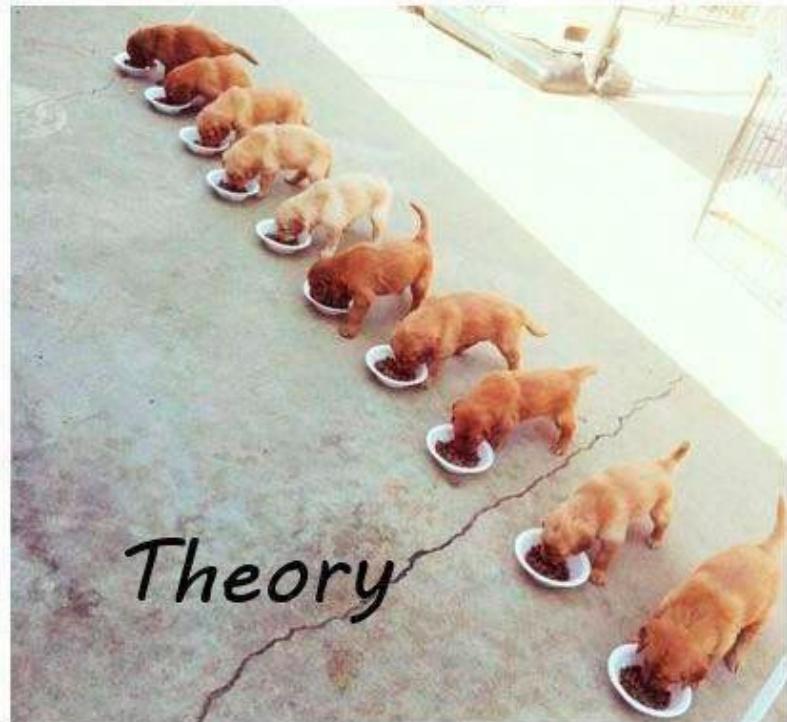

- Explain why different languages exist.
- Differentiate syntax and semantics.
- Describe how static and dynamic typing are different.
- Understand how static analysis works.
- Explain how linting is used to improve the quality of most software systems.
- Describe why async functions exist.
- Describe how async functions execute in Node/browser.
- Be able to write and understand straightforward functions using `async/await`, promises, and callbacks.

# Async

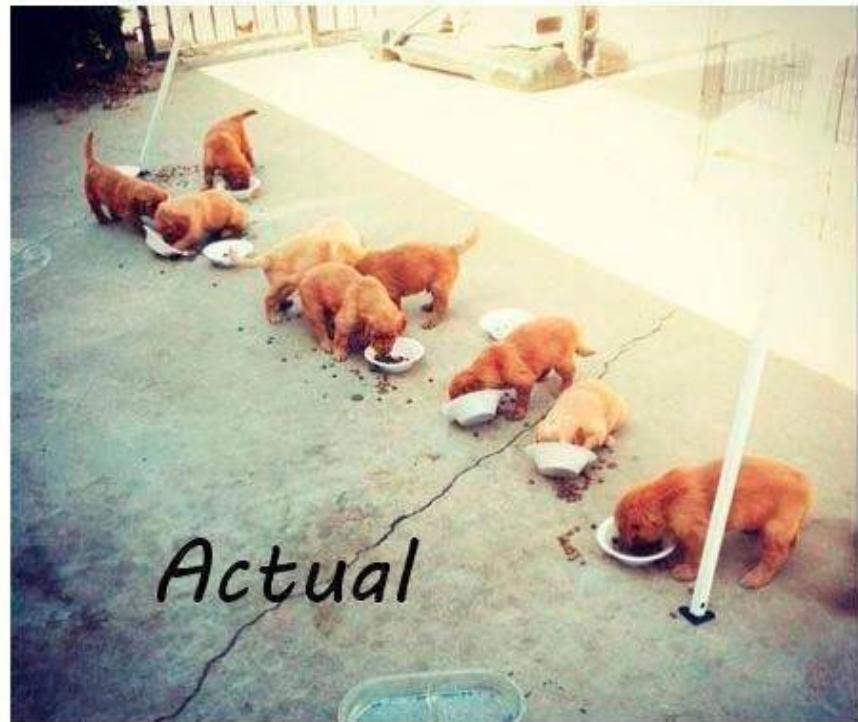

# Node JS Learning Curve

# Multithreaded programming

Theory

Actual

# Concurrency

- What is concurrency?
  - Executing multiple program parts at the same time.
  - Actual ordering is indeterminate.
- Why is it hard?
  - Shared state! W before R diff than R before W
  - Deadlock / live lock / resource starvation
- Why would we ever want to run code concurrently?
  - Computation gains driven by cores; avoids blocking

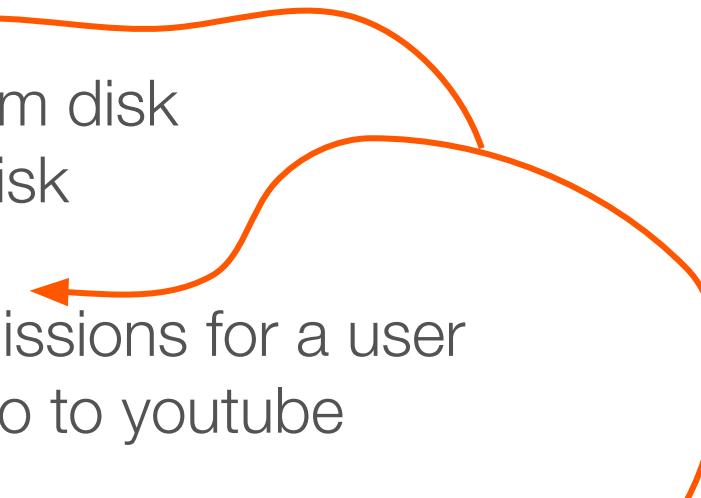

# Why is blocking a problem?

<http://rbyers.github.io/scroll-latency.html>

# Async is for long running processes

- setTimeout ()
- File I/O
  - Reading a file from disk
  - Writing a file to disk
- Network Requests
  - Getting the permissions for a user
  - Uploading a video to youtube

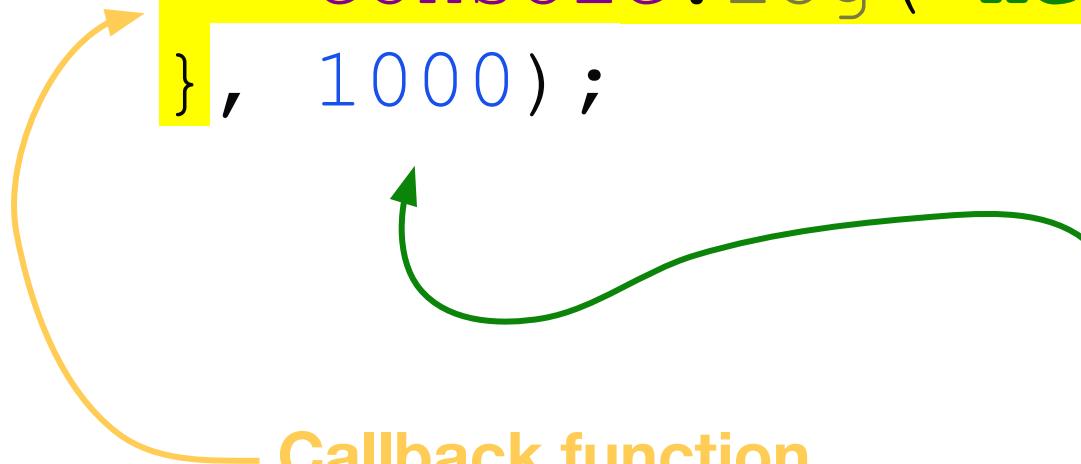

Used in the project!

# `setTimeout(...)`

```
setTimeout(function () {
    console.log("Hello");
}, 1000);
```

# setTimeout(...)

```
setTimeout(function () {  
    console.log("Hello");  
}, 1000);
```

After 1000ms (1s),  
execute the **callback  
function**.

```
function start() { doIt(); }

function doIt() {
  console.log('start');
  setTimeout(function() {
    console.log('done');
  }, 2000);
  console.log('end');
}

start();
```

What will the output be?

# Why would we do this?

```
function makeItSo() {  
    ...  
    setTimeout(function() {  
        // do the long thing  
    }, 0);  
    ...  
}
```

# Anatomy of a callback

```
const onComplete = function() {  
    // function assigned to a var!  
};  
  
setTimeout(onComplete, 100);
```

# Error-first callback idiom

```
foo.action(msg, function(err, data) {  
    if (err) {  
        // handle  
        return;  
    } else {  
        // worked, use data  
    }  
}) ;
```

# Non-trivial example

Read first file  
in a directory.

# Non-trivial example

Read first file  
in a directory.

```
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
    const data = fs.readFile(files[0]);
    // process data
}
```

# Non-trivial example

Read first file  
in a directory.

```
const files = fs.readdir(source);  
if (fs.stat(files[0]).isFile()) {  
    const data = fs.readFileSync(files[0]);  
    // Process data  
}
```

**Remember!**  
**File I/O is Asynchronous**

# Non-trivial example

Read first file  
in a directory.

```
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
    const data = fs.readFile(files[0]);
    // process data
}
```

We need to *handle*  
these methods

# We can handle async... I *promise*

callbacks

Pre-2015(ish)

promises

2009-2015

async &  
await

2017

# We can handle async... I *promise*

callbacks

Pre-2015(ish)

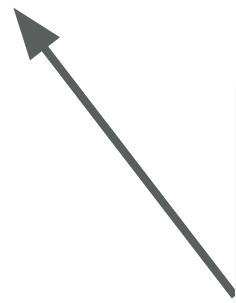

```
setTimeout(function() {  
    console.log("Hello");  
}, 1000);
```

Callback  
function

```
fs.readdir(source, function(err, files) {
```

# callbacks

Read first file  
in a directory.

```
// if this were synchronous
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
  const data = fs.readFile(files[0]);
  // process data
}
```

```
fs.readdir(source, function(err, files) {  
  if (err) {  
    // handle  
  } else {
```

# callbacks

See if it worked

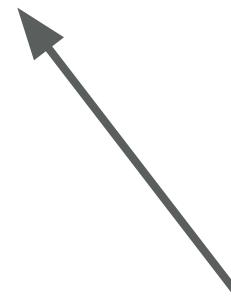

```
// if this were synchronous  
const files = fs.readdir(source);  
if (fs.stat(files[0]).isFile()) {  
  const data = fs.readFile(files[0]);  
  // process data  
}
```

```
fs.readdir(source, function(err, files) {  
  if (err) {  
    // handle  
  } else {  
    fs.stat(files[0], function(err, stat) {  
      if (err) {  
        // handle  
      } else {
```

# callbacks

Check if it's a  
file

```
// if this were synchronous  
const files = fs.readdir(source);  
if (fs.stat(files[0]).isFile()) {  
  const data = fs.readFile(files[0]);  
  // process data  
}
```

# callbacks

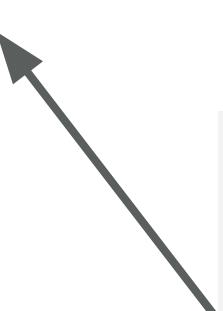

```
fs.readdir(source, function(err, files) {  
  if (err) {  
    // handle  
  } else {  
    fs.stat(files[0], function(err, stat) {  
      if (err) {  
        // handle  
      } else {  
        if (stat.isFile()) {  
          fs.readFile(files[0], function(err, data) {  
            if (err) {  
              // handle  
            } else {  
              // process data  
            }  
          }  
        }  
      }  
    })  
  }  
})
```

Read the file

```
// if this were synchronous  
const files = fs.readdir(source);  
if (fs.stat(files[0]).isFile()) {  
  const data = fs.readFile(files[0]);  
  // process data  
}
```

```
fs.readdir(source, function(err, files) {  
  if (err) {  
    // handle  
  } else {  
    fs.stat(files[0], function(err, stat) {  
      if (err) {  
        // handle  
      } else {  
        if (stat.isFile()) {  
          fs.readFile(files[0], function(err, data) {  
            if (err) {  
              // handle  
            } else {  
              // process data  
            }  
          }) ;  
        }  
      }  
    }) ;  
  }  
}) ;
```

```
// if this were so  
const files = fs.readdirSync(source);  
if (files.length === 0) {  
  console.log('No files found');  
}  
const data = fs.readFileSync(files[0]);  
// process data
```

# callbacks

Add many  
braces

```
// if this were synchronous
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
  const data = fs.readFile(files[0]);
  // process data
}
```

# callbacks

Add many  
braces

```
fs.readdir(source, function(err, files) {  
  if (err) {  
    // handle  
  } else {  
    fs.stat(files[0], function(err, stat) {  
      if (err) {  
        // handle  
      } else {  
        if (stat.isFile()) {  
          fs.readFile(files[0], function(err, data) {  
            if (err) {  
              // handle  
            } else {  
              // process data  
            }  
          }) ;  
        }  
      }  
    }) ;  
  }  
}) ;
```

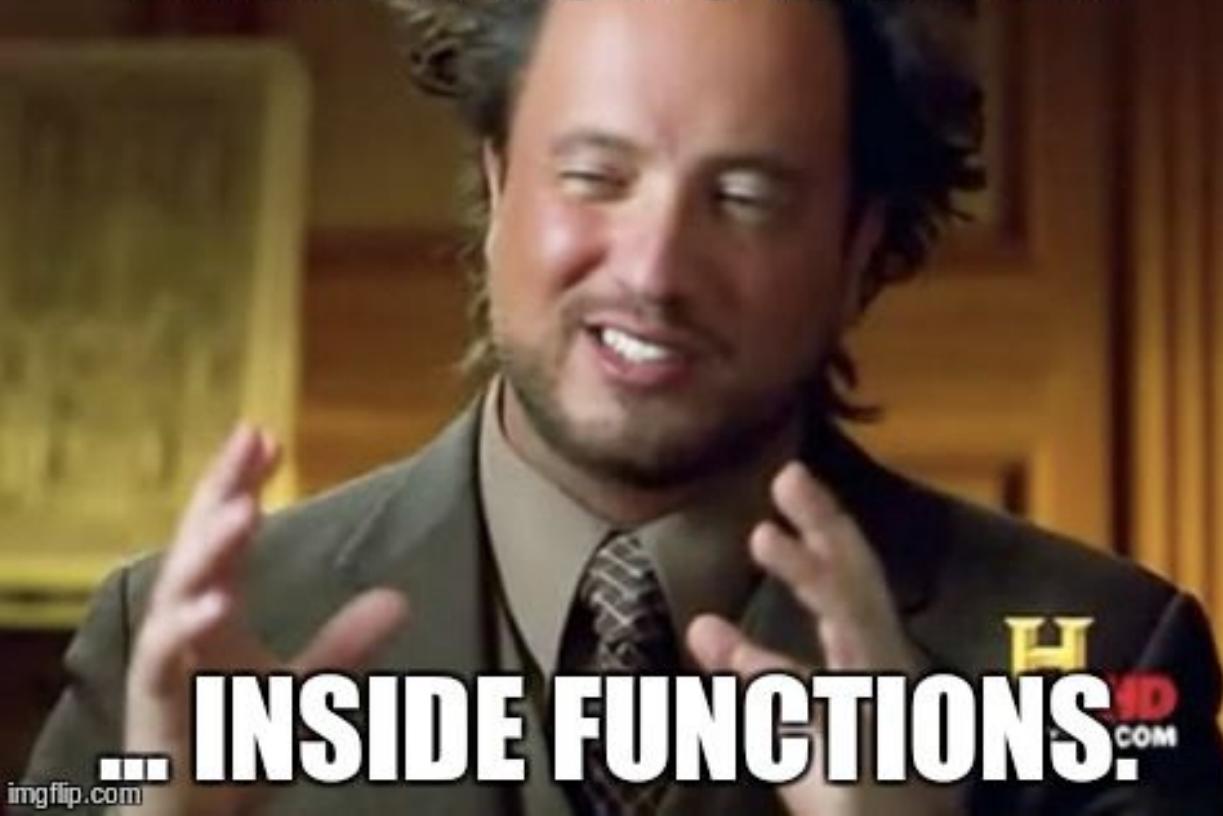

```
// if this were synchronous  
const files = fs.readdir(source);  
if (fs.stat(files[0]).isFile()) {  
  const data = fs.readFile(files[0]);  
  // process data  
}
```

# Classy Team Provisioning

- Provisioning the projects:
  - 1) Get the Classy data [getCourse(name, cb) ]
  - 2) In a huge loop:
    - a) Create a repo [createRepo(name, cb) ]
    - b) Import the base repo [importRepo(repo, import, cb) ]
    - c) Create the team [createTeam(name, cb) ]
    - d) For each team member:
      - Add member to the team [addMember(team, name, cb) ]
      - e) Put the team on the repo [addTeam(repo, team, cb) ]
      - f) Find the staff team [findTeam(name, cb) ]
      - g) Put the staff team on the repo [addTeam(repo, team, cb) ]

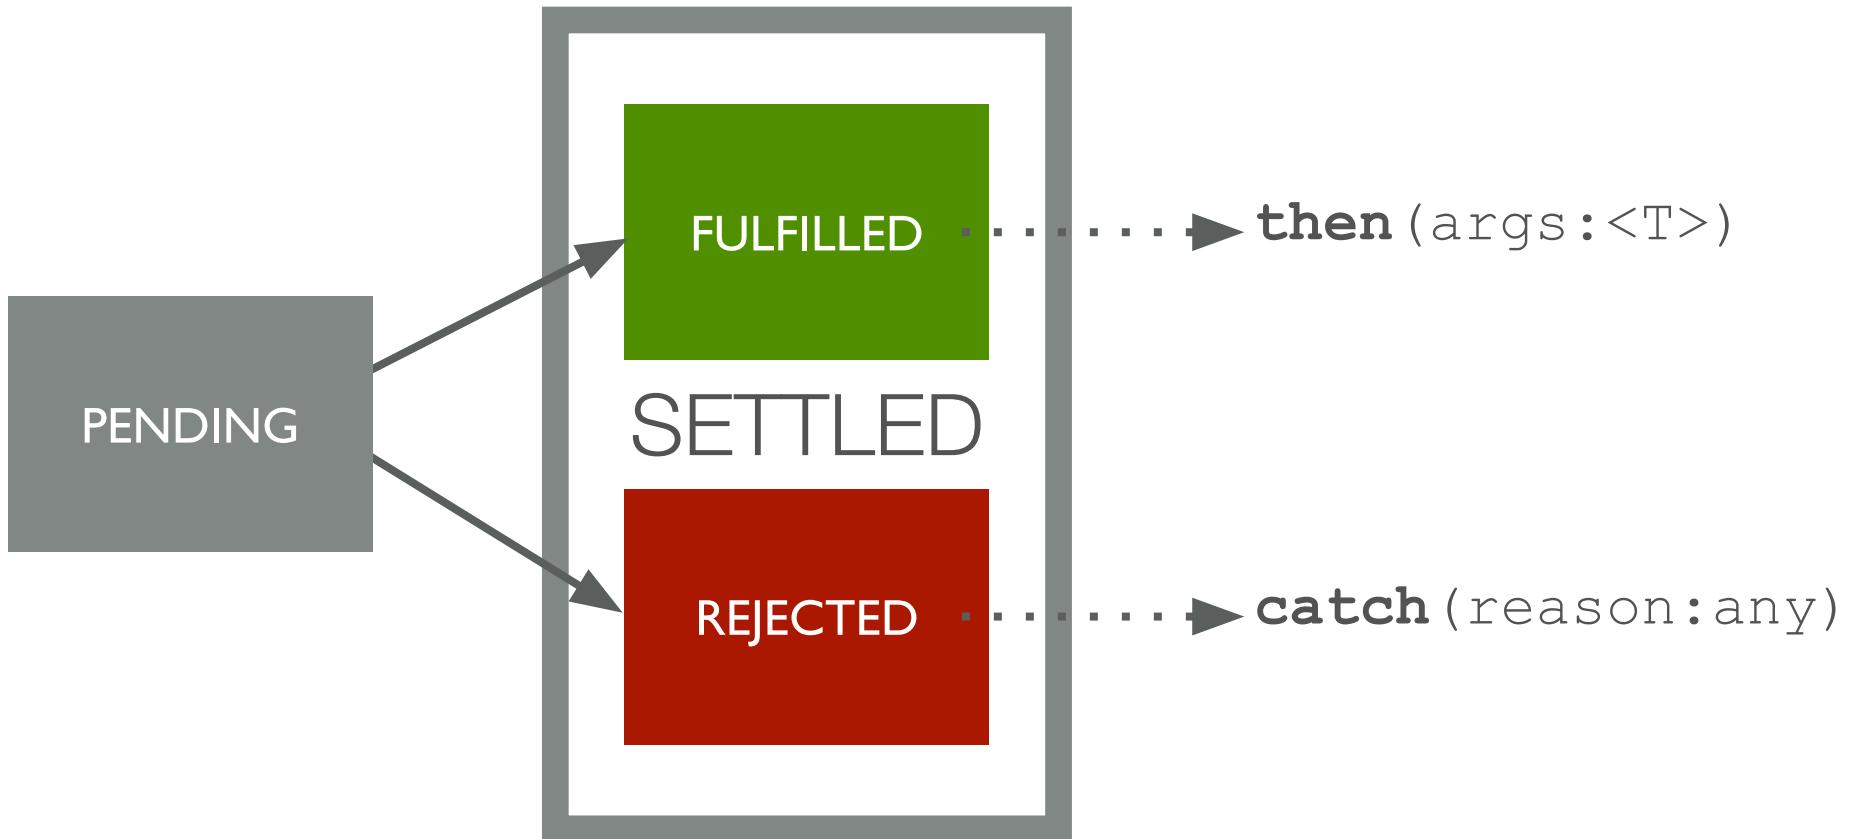

I'VE GOT FUNCTIONS  
INSIDE FUNCTIONS...

imgflip.com

# Promise execution states

# Promises (simplified)

    then(result: <T>): Promise<T>;  
    catch(reason: any): Promise<T>;  
}
```

# Comparing to callbacks

callbacks

```
fs.readdir(source, function(err, files)
{
  if (err) {
    // handle error
  } else {
    // handle success
  }
})
```

promises

```
fs.readdir(source)
```

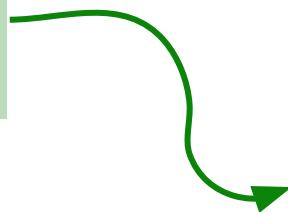

# Comparing to callbacks

callbacks

```
fs.readdir(source, function(err, files)
{
  if (err) {
    // handle error
  } else {
    // handle success
  }
}
```

promises

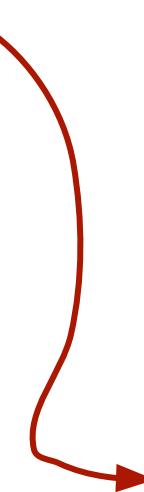

```
fs.readdir(source).then((files) => {
  // handle success
}) ;
```

# Comparing to callbacks

callbacks

```
fs.readdir(source, function(err, files)
{
  if (err) {
    // handle error
  } else {
    // handle success
  }
})
```

promises

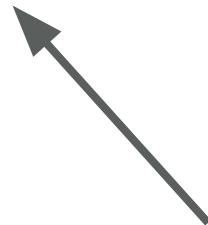

```
fs.readdir(source).then((files) => {
  // handle success
}) .catch((err) => {
  // handle error
});
```

# Revisiting reading file

```
let file;  
fs.readdir(source)
```

promises

Read first file  
in a directory.

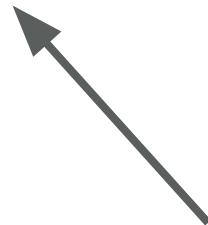

```
// if this were synchronous  
const files = fs.readdir(source);  
if (fs.stat(files[0]).isFile()) {  
  const data = fs.readFile(files[0]);  
  // process data  
}
```

# Revisiting reading file

```
let file;  
fs.readdir(source).then(function(files) {  
  file = files[0];  
  return fs.stat(file);  
})
```

promises

Check if it's a  
file

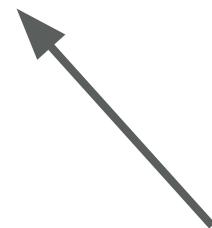

```
// if this were synchronous  
const files = fs.readdir(source);  
if (fs.stat(files[0]).isFile()) {  
  const data = fs.readFile(files[0]);  
  // process data  
}
```

# Revisiting reading file

promises

```
let file;
fs.readdir(source).then(function(files) {
  file = files[0];
  return fs.stat(file);
}).then(function(fileStat) {
  if (fileStat.isFile())
    return fs.readFile(file);
})
```

Read the file

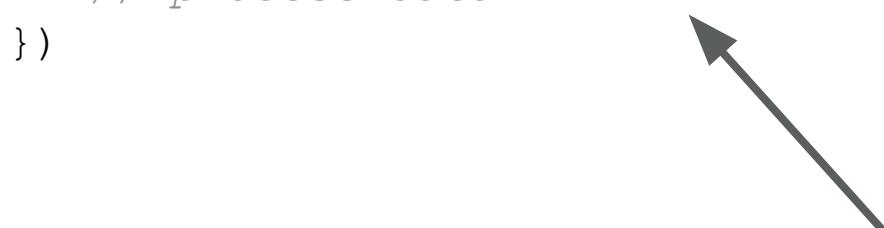

```
// if this were synchronous

// if this were synchronous
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
  const data = fs.readFile(files[0]);
  // process data
}
```

# async & await

- Syntactic sugar, TS compiles these to promises:

**async** // declare that a result  
will eventually be returned

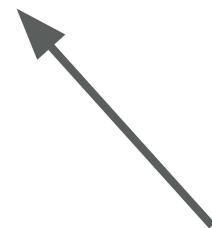

**await** // tell the code to  
suspend execution until result  
exists

# Revisiting reading file

```
const files = await fs.readdir(source);
```

async/await

Read first file  
in a directory

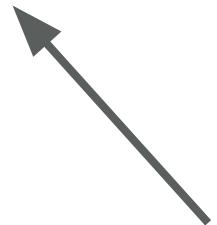

```
// if this were synchronous
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
  const data = fs.readFile(files[0]);
  // process data
}
```

# Revisiting reading file

async/await

```
const files = await fs.readdir(source);  
const file = files[0];
```

Read first file  
in a directory

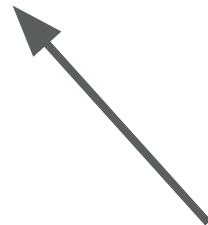

```
// if this were synchronous  
const files = fs.readdir(source);  
if (fs.stat(files[0]).isFile()) {  
  const data = fs.readFile(files[0]);  
  // process data  
}
```

# Revisiting reading file

async/await

```
const files = await fs.readdir(source);
const file = files[0];
const fileStat = await fs.stat(file);
```

Check if it's a  
file

```
// if this were synchronous
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
  const data = fs.readFile(files[0]);
  // process data
}
```

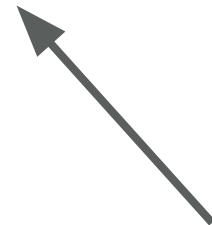

# Revisiting reading file

async/await

Check if it's a  
file

```
const files = await fs.readdir(source);
const file = files[0];
const fileStat = await fs.stat(file);

if (fileStat.isFile()) {
```

```
// if this were synchronous
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
  const data = fs.readFile(files[0]);
  // process data
}
```

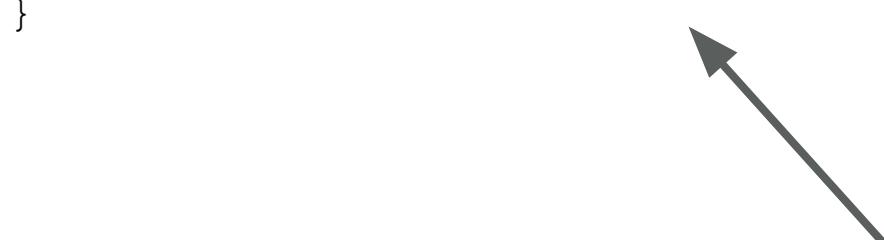

# Revisiting reading file

async/await

```
const files = await fs.readdir(source);
const file = files[0];
const fileStat = await fs.stat(file);

if (fileStat.isFile()) {
  const fileData = await fs.readFile(file);
  // process data
}
```

Process Data

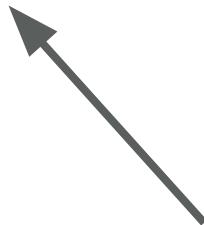

```
// if this were synchronous
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
  const data = fs.readFile(files[0]);
  // process data
}
```

# Revisiting reading file

async/await

```
try {  
    const files = await fs.readdir(source);  
    const file = files[0];  
    const fileStat = await fs.stat(file);  
  
    if (fileStat.isFile()) {  
        const fileData = await fs.readFile(file);  
        // process data  
    }  
} catch(err) {  
    // handle errors  
}
```

Handle Errors

```
// if this were synchronous  
const files = fs.readdir(source);  
if (fs.stat(files[0]).isFile()) {  
    const data = fs.readFile(files[0]);  
    // process data  
}
```

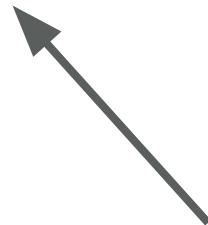

# Revisiting reading file

async/await

```
try {
  const files = await fs.readdir(source);
  const file = files[0];
  const fileStat = await fs.stat(file);

  if (fileStat.isFile()) {
    const fileData = await fs.readFile(file);
    // process data
  }
} catch(err) {
  // handle errors
}
```

Handle Errors

```
// if this were synchronous
const files = fs.readdir(source);
if (fs.stat(files[0]).isFile()) {
  const data = fs.readFile(files[0]);
  // process data
}
```

# What about **async**?

The function returns a promise

```
async function readDirectory() {  
    try {  
        let file;  
        const files = await fs.readdir(source);  
        const file = files[0];  
        const fileStat = await fs.stat(file);  
  
        ...  
    }  
}
```

```
fs.readdir(source).then(function(files) {  
    file = files[0];  
    return fs.stat(file);  
}).then(function(fileStat) {  
    if (fileStat.isFile())  
        return fs.readFile(file);  
}).then(function(fileData) {  
    // process data  
}).catch(function(err) {  
    // handle errors  
});
```

```
try {  
    const files = await fs.readdir(source);  
    const fileStat = await stat(files[0]);  
    if (fileStat.isFile())  
        const fileData = await fs.readFile(file);  
        // process data  
    }  
} catch(err) {  
    // handle errors  
}
```

```
fs.readdir(source, function (err, files) {  
    if (err) {  
        // handle errors  
    } else {  
        fs.stat(files[0], function(err, stat) {  
            if (err) {  
                // handle errors  
            } else {  
                if (stat.isFile()) {  
                    fs.readFile(files[0],  
                        function(err, data) {  
                            if (err) {  
                                // handle errors  
                            } else {  
                                // process data  
                            }  
                        })  
                }  
            }  
        });  
    }  
});
```

# Promises (simplified)

```
// all must pass, else catch
// best choice if complete success is required
Promise.all(promiseList: <T>[]): Promise<T>

// always then, but with status for each promise
// best choice for large queues where retries are ok
Promise.allSettled(promiseList: <T>[]): Promise<T>

// first complete
// rarely used, but sometimes handy
Promise.race(promiseList: <T>[]): Promise<T>
```

# Await/Promises and performance/errors

- Promises:
  - Promisified code does not block main thread.
  - Rejected promises will fail silently if not caught.
  - [Playground Example](#)
- Async/await:
  - Async code is executed sequentially but does not block main thread.
  - Async errors will fail silently if not caught.
  - Async errors need to be caught in async functions
  - [Playground Example](#)

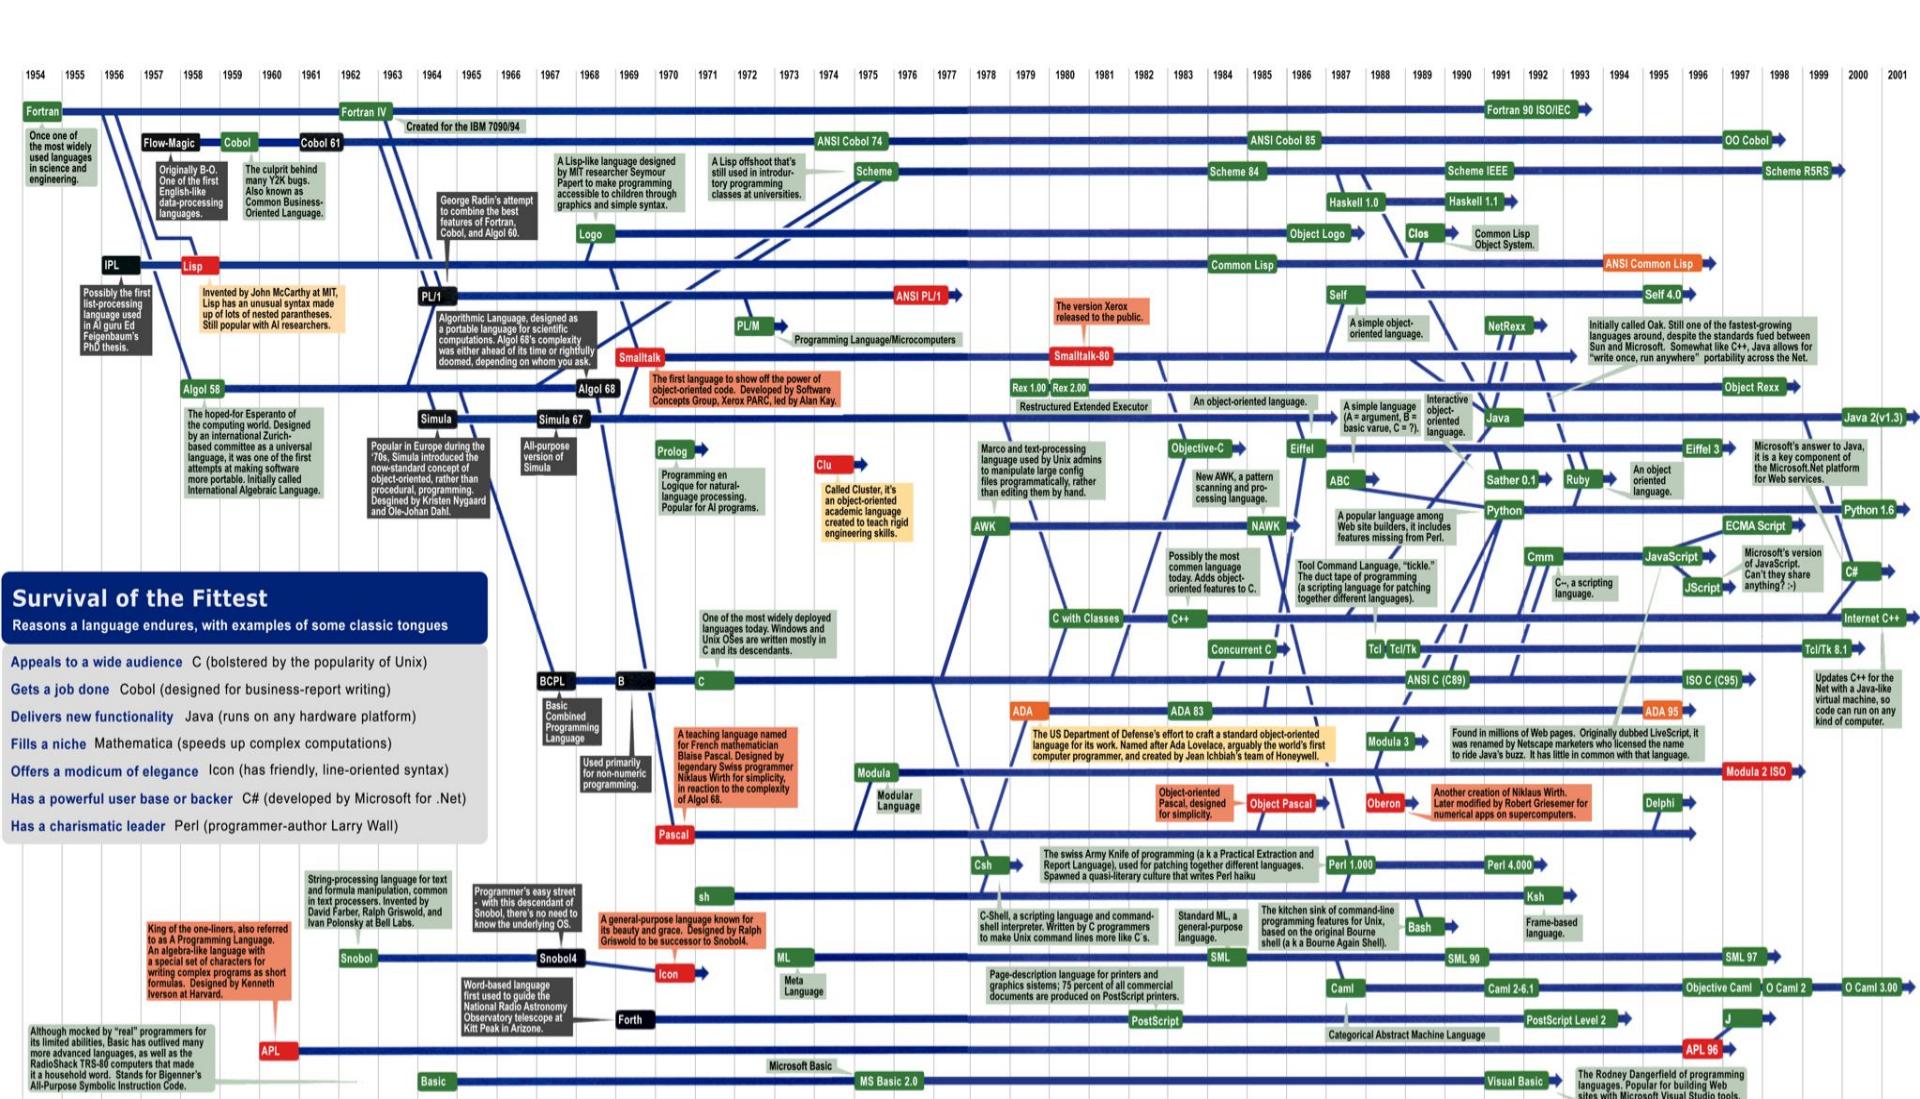

# Languages

# What does a programming language do?

The process of **transforming a mental plan** of desired actions for a computer **into a representation that can be understood by the computer.**

— Jean-Michel Hoc and Anh Nguyen-Xuan

# What does this program do?

```
Multp: .equ 32

Z : number = x \* y;

# Static vs dynamic types

*Variables have types in statically typed languages.*

Java:

- `int age;`
- Compiler enforces consistency:
  - `age = 1; // ok`
  - `age = false; // !ok`

# Static vs dynamic types

*Variables have types in statically typed languages.*

TypeScript:

- `let age: number;`
- Compiler enforces consistency:
  - `age = 1; // ok`
  - `age = false; // !ok`

# Static vs dynamic types

*Variables have types in statically typed languages.*

*Values have types in dynamically typed languages.*

## TypeScript:

- `let age: number;`
- Compiler enforces consistency:
  - `age = 1; // ok`
  - `age = false; // !ok`

- `JavaScript:`
  - `var age = 1;`
  - `age = 100; // number`
  - `age = false; // boolean`
  - `age = "CPSC"; // string`

# Static vs dynamic types

*Variables have types in statically typed languages.*

TypeScript is *optionally* statically typed.

## TypeScript:

- `let age: number;`
- Compiler enforces consistency:
  - `age = 1; // ok`
  - `age = false; // !ok`

- TypeScript type Inference:
  - `let age = 1; // number`
  - `age = 100; // ok`
  - `age = false; // !ok`
  - `age = "CPSC"; // !ok`

# Binding context

function () {} vs. () => {}

- JavaScript syntax has evolved over many years.
  - E.g., callbacks -> promises -> async/await
- Variable scoping issues led to ‘fat arrow’ notation:

```
class DataProcessor {  
    private data = 0;  
  
    public compute() {  
        console.log(this.data);  
        setTimeout(function() {  
            this.data++;  
            console.log(this.data);  
        }, 0);  
        console.log(this.data);  
    }  
  
    const proc = new DataProcessor();  
    proc.compute()
```

```
class DataProcessor {  
    private data = 0;  
  
    public compute() {  
        console.log(this.data);  
        setTimeout(() => {  
            this.data++;  
            console.log(this.data);  
        }, 0);  
        console.log(this.data);  
    }  
  
}
```

# Value comparison (`==` vs `====`)

```
if (x === y) {  
    console.log("x and y are strictly equal");  
}  
if (x == y) {  
    console.log("x and y are loosely equal");  
}  
  
undefined == null; // true  
undefined === null; // false  
  
1 == '1'; // true  
1 === '1'; // false
```

# Static Analysis

# Syntax & semantics

- Syntax defines the set of valid tokens that are allowed.
  - ‘if (token === token)’ is syntactically valid.
- Semantics define what the tokens actually mean.
  - ‘if (token === token)’ is semantically meaningless.
- Compilers check for valid syntax (e.g., javac, tsc).
- Semantics will mostly be evaluated at runtime.
  - e.g. by using or testing the system.
  - Linters can detect some semantic issues before runtime.

# Static analysis: Formatting & linting

- Static analyses are any programmatic analysis of a program that only inputs the program text itself and does not need to execute the program.
- Dynamic analyses need to run the program, so also require inputs (often via test cases or fuzzing).
- Static analyses are performed in compilation, but also during:
  - Formatting: enforcing consistent code *syntax*
    - Tabs vs spaces, line length, whitespace, etc
    - Aids collaboration and readability
  - Linting: enforcing good *semantics* of code
    - No unused vars, no globals, no misused promises
    - Prevents bugs

# Linting example

```
const promise = Promise.resolve('value');

if (promise) {
    // do something
}

const val = promise ? 123 : 456;

while (promise) {
    // do something
}
```

What is wrong  
with this code?

# Linting example

```
const promise = Promise.resolve('value');

if (promise) ←
  // do something
}

const val = promise ? 123 : 456;

while (promise) { ←
  // do something
}
```

These are still promises (not values!)

# We can catch this with lint!

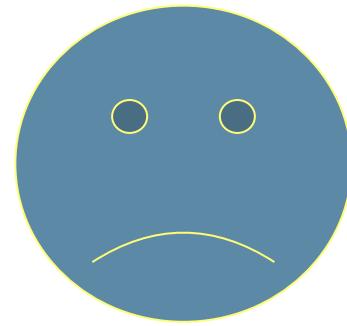

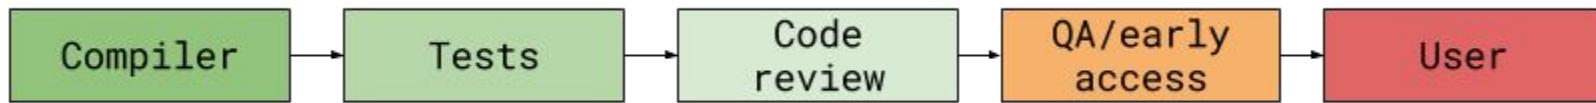

```
}

This condition will always return true since this 'Promise<string>' is always defined. ts(2801)
IIInsightFacade.ts(16, 5): Did you forget to use 'await'?

const promise: Promise<string>

cons View Problem (F8) Quick Fix... (⌘.)
if (promise) {
    // Do something
}
const val = promise ? 123 : 456;
while (promise) {
    // Do something
}
```

# Move bugs to the left

<https://samwho.dev/blog/move-your-bugs-to-the-left/>

# Linters help developers:

- Avoid some semantic errors
- Ensure code consistency
  - Don't need to think about representation
  - E.g., naming conventions: camelCase vs PascalCase vs snake\_case
- Improve code comprehension
  - Consistent code is easier for other developers (including future you) to understand
  - E.g., const vs let; function return types
- Improve design
- Ease evolution
- Reduce bloat

# Linting: Error avoidance

It can be easy to write syntactically valid code that introduces subtle semantic errors.

Example: avoid using await inside a for loop.

```
const files = await fs.readdir(source);  
for (const file of files) {  
    const content = await fs.readFile(file);  
}
```

This code seems to run... a bit slow?

# Linting: Code consistency

Conventions make it simpler for developers write code with less mental effort.

Example: use a single naming convention.

```
const userName;
```

```
const Password;
```

```
const display_name;
```

What do I name the next variable to hold an email address?

# Linting: Code comprehension

Enforce code that is easy for other developers (including future you) to understand.

```
// specify function return types
async function getContent(name: string) {
  const buffer = await fs.readFile(name);
  return buffer.toString("base64");
}
```

// prefer const.

```
let PI = 3.14;
```

Should the value for PI  
ever be reassigned?

What do I get if I call  
getContent(..)?

# Linting: Code evolution

Decisions that you make today can lead to unexpected errors in the future when more code is added.

Example: always use braces for single-line if statements.

```
if (user.isAdmin)  
    grantFullAccess(user);
```

What happens if I add a  
console.log(..)  
statement above  
grantFullAccess(..)?

# Linting: Security

- Linters can also check for some security vulnerabilities.

```
// @no-eval
```

```
public myAction(action: string) { eval(action); }  
myAction("console.log('hi 310!')"); //
```

# Linting: Security

- Linters can also check for some security vulnerabilities.

```
// @no-eval
```

```
public myAction(action: string) { eval(action); }
myAction("console.log('hi 310!')");           //
myAction("await fs.remove('/home/' +
  "{ recursive: true, force: true }");")
```

# Linting: Security

- Linters can also check for some security vulnerabilities.

```
// @no-eval
public myAction(action: string) { eval(action); }
myAction("console.log('hi 310!')");           //
myAction("await fs.remove('/home/' +
  "{ recursive: true, force: true }");")
```

```
// @security/detect-object-injection
public handler(key:string, value:string) {
  this.authenticatedUser[key] = value;
}
handler("isAuthenticated", "true");
```

# Refactoring

KEEP  
CALM  
AND  
REFACTOR  
(AGAIN)

# Current status

- Due tomorrow @ 1800.
- J1: due in 8 days @ 1800.
- C2: Released before the first lab on Monday.
  - Looking at this will be crucial for completing your J1 user stories.

# Current status

- Due tomorrow @ 1800.
- J1: due in 8 days @ 1800.
- C2: Released before the first lab on Monday.
  - Looking at this will be crucial for completing your J1 user stories.
- LA buckets: First release by tomorrow.
  - Not all LA's have had enough coverage to be released.
  - Each update can update all previously-released LAs (up or down).
    - Tomorrow (Q0, J0):
      - LA1: Testing (sufficient coverage)
    - After Q1 & J1:
      - LA0: Process
      - LA4: Construction
    - After Q2, J2:
      - LA2: High Level Design
      - LA5: Security & Ethics
    - After Q3, J3:
      - LA3: Low Level Design

# Examinable skills

You should be able to...

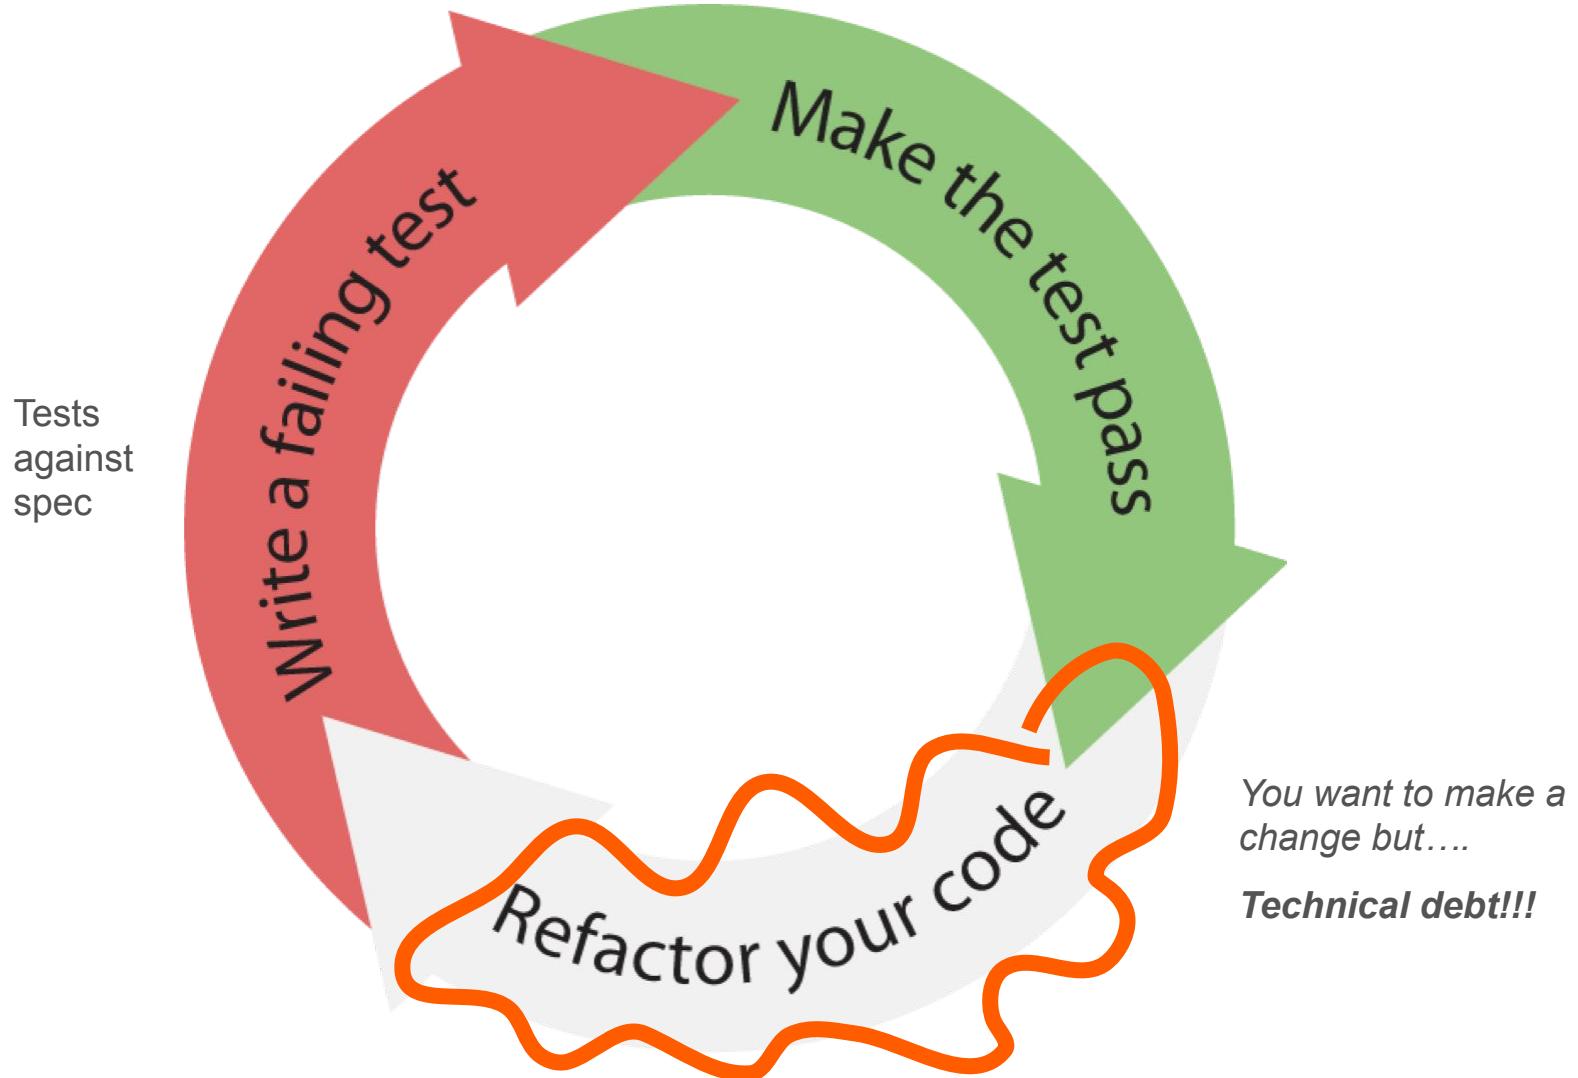

- Explain what technical debt and code smells are.
  - Be able to describe how these challenges emerge as code evolves.
- Explain the concept of refactoring.
- Explain when to refactor and when not to refactor.
- Identify code smells and be able to identify and carry out appropriate refactorings:
  - Feature envy/Law of Demeter violation → move method and where to put the new method.
  - Magic numbers → Constants or variables.
  - Comments → extract methods and pipe through parameters.
  - Same method in multiple subclasses → pull up method.
  - Almost duplicate code → refactor to template.
  - Switch on type → refactor to use polymorphism.
  - Divergent changes → extract class.
  - Shotgun surgery → introduce class(es) and move methods.
  - Long Methods → introduce sub-methods.
  - Long Parameter List → introduce class for parameters.
- Explain that the underpinning principle of design is that changes should be as localised as possible.
- Achieve well named methods, identify method aesthetics, and when they are violated.
- Be able to decrease feature envy by moving a method and know where to put the new method(s).
- Be able to identify and fix of violations of the Law of Demeter.

# Agile software process: A deeper look

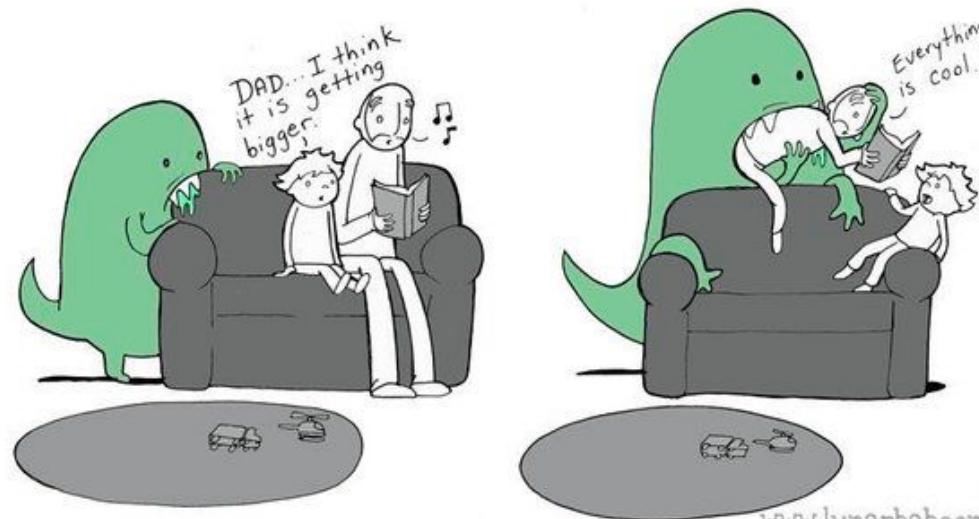

Test driven design (write tests first).

Emergent design: Start at the Minimum Viable Product, then grow from there, identifying duplication and introducing abstractions as needed so solve duplication.

**Refactor code:** rather than doing big design first (make pragmatic choices along the way -- this is not a license to write terrible code) AND the architectural spike must come first.

# Technical debt

# “Listening” to code

# “Listening” to code

Code  
smell

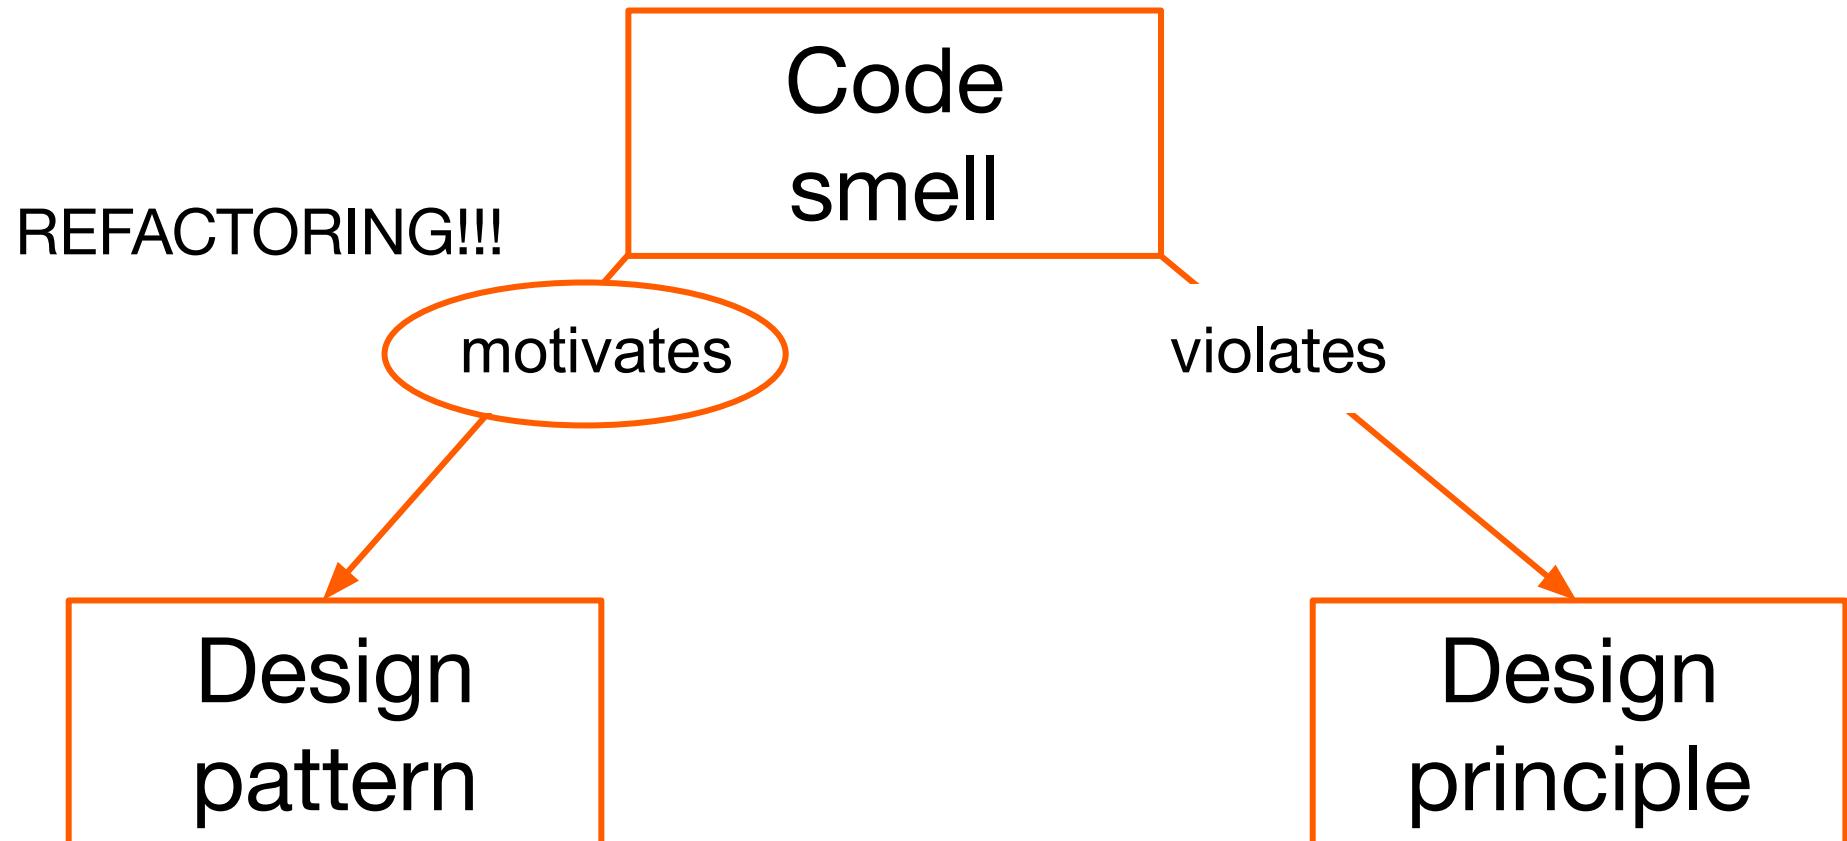

# “Listening” to code

Code  
smell

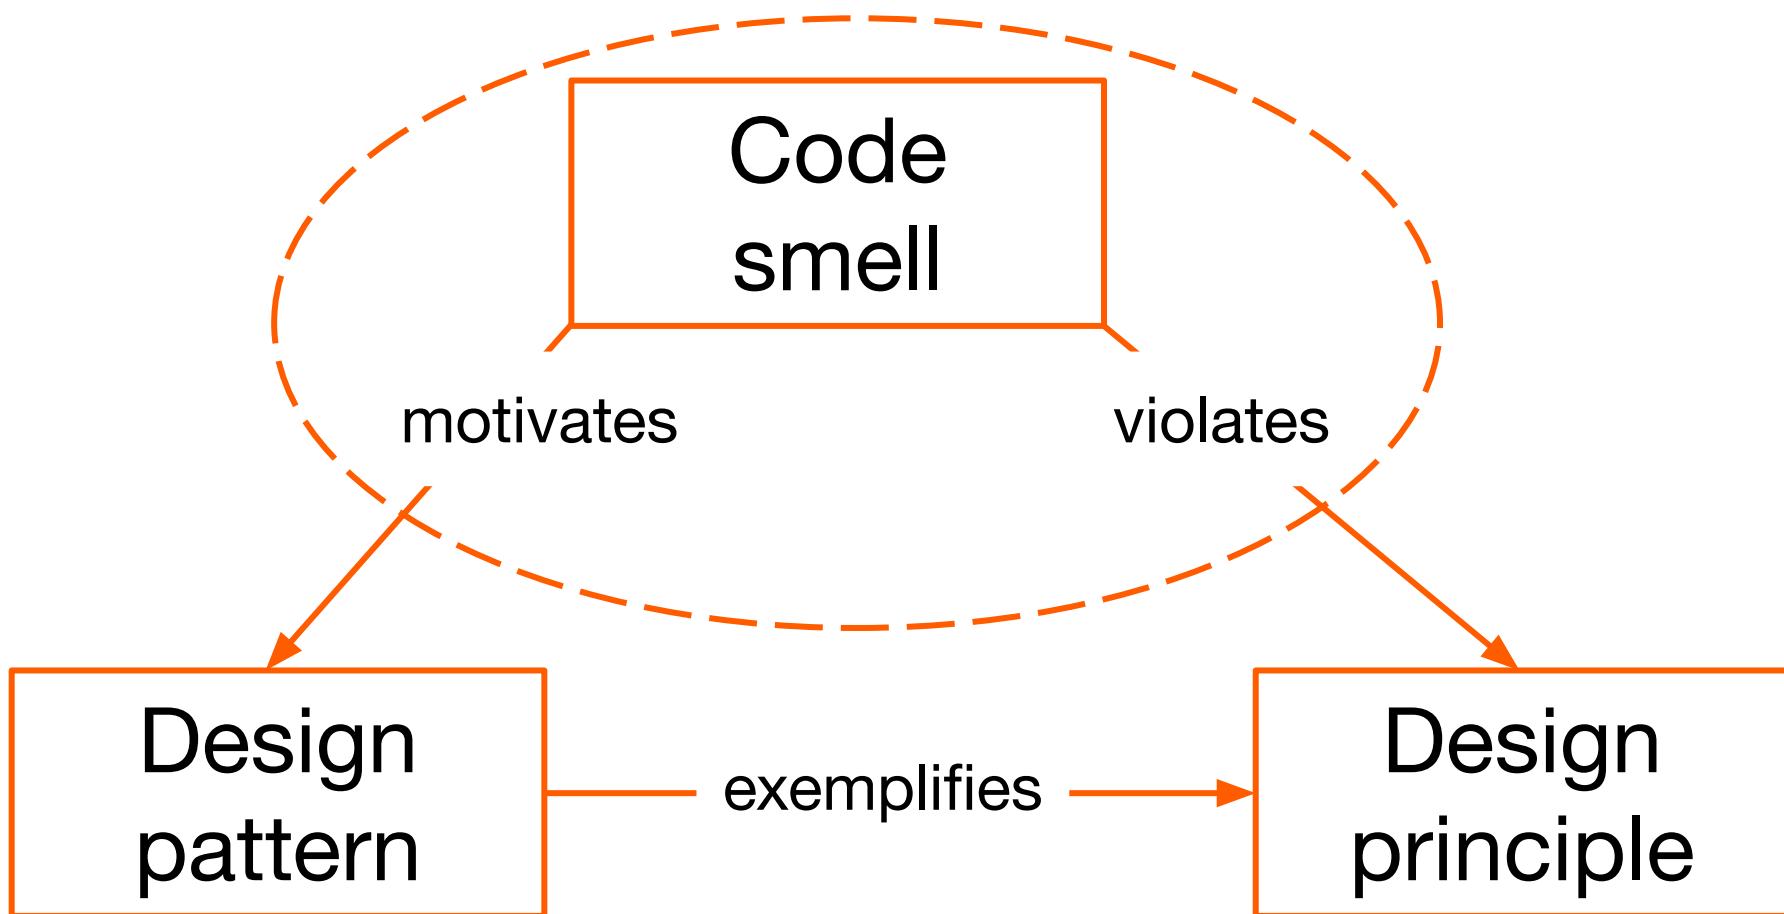

violates

Design  
principle

# “Listening” to code

# “Listening” to code

# Refactoring timeline

- NOT:
  - 2 weeks of every 6 months.
  - When the tests are failing.
  - When you should just rewrite the code.
  - When you fix a bug.
- Instead, opportunistically during development:
  - If you recognize a warning sign (smell).
  - Before you start a new function.
  - After you finish a new function.
  - When you review code/your code is reviewed.

# What is refactoring?

Predictable and  
meaning\* preserving  
code transformations.

\*meaning == semantics == behaviour

# Craftsmanship manifesto

Not only working software,  
but also well-crafted software;  
Not only responding to change,  
but also steadily adding value.

# Broken code

- Code must be able to do three things; if any of these are missing, it can be considered broken:
  - Its job (execute according to its purpose).
  - Afford change.
  - Be understandable.

```
// ex 1:  
q= ((p<1) ? (p?0:1) : (p==4) ? 2 : (p+1));  
  
// ex 2:  
while (*a++ = *b--);  
  
// ex 3:  
while (n--) {  
    for (s=t,d=e; *s; s++) {  
        for (p=v+3; *p; p++) {  
            // ... and more  
        }  
    }  
}
```

```
1 // This function takes in name as a parameter
2 // and logs a string which greets that name
3 // using the information passed
4 function sayHi(name) {
5   console.log("Hi" + name + ", nice to meet you." )
6 }
7
8 sayHi("Sam");
```

Minified Code

```
1 function sayHi(o){console.log ("Hi"+o+", nice to meet you.") }sayHi("Sam");
```

<https://www.cloudflare.com/learning/performance/why-minify-javascript-code/#:~:text=This%20includes%20the%20removal%20of,results%20in%20compact%20file%20size.&text=Minification%20speeds%20up%20webpage%20loading,visitors%20and%20search%20engines%20happy.>

# Technical debt

Design choices that were made in the interest of time or budget, rather than **technical reasons**.

These accrue over time and often require broad system restructuring to decrease debt introduced by past poor decisions.

*Technical debt needs to be allocated on a different “budget” or put into an engineering task and discussed with the customer so that they can decide about its value.*

*Additionally - some technical debt related user stories can exist, in which case you might see the “user” as a subsystem. “As the payment system, I need refactoring of the underlying code to facilitate the x change to the costing algorithm”. This is sometimes a necessity, but not the norm.*

Reckless

Accidental

1.

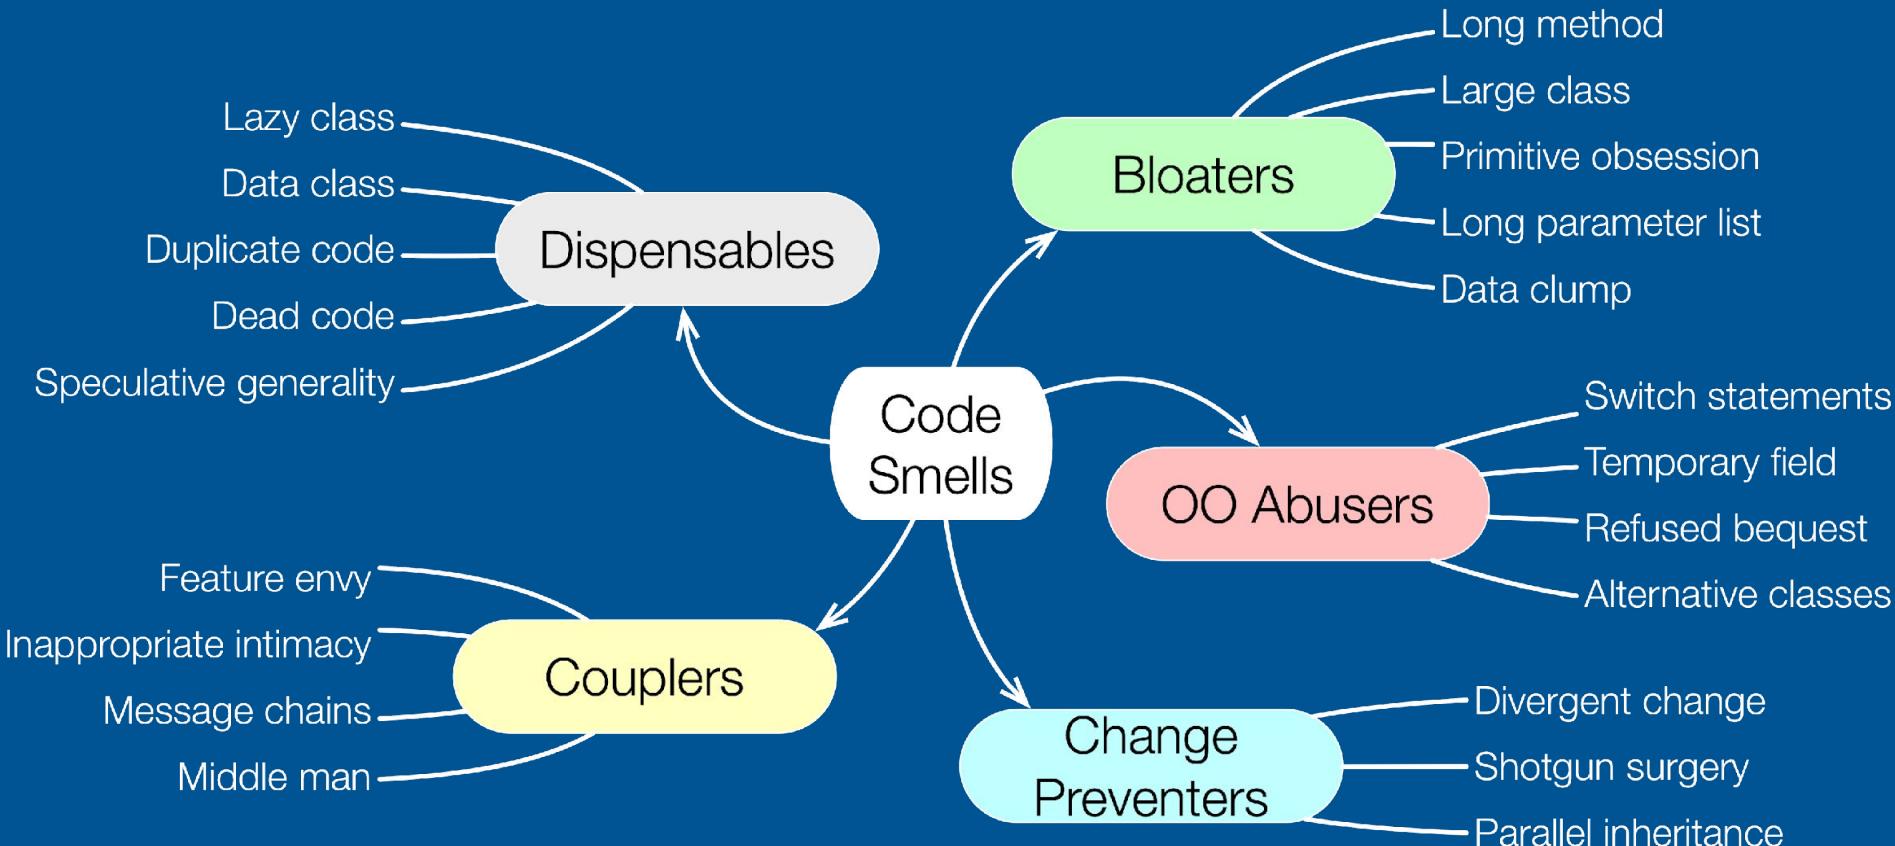

# 2 Tricks of Agile:

- 1) TESTS. Write tests that ensure that you know that your code is meeting spec (or the tests fail until you meet spec).
- 2) Fluency with REFACTORING.

# Symptoms of technical debt

# Motivation for refactoring ...

- As the code changes, code issues emerge.
- If it's larger scale it's called **Technical Debt**.
- If it's a cosmetic issue you can see, it's called a **Code Smell**.
- Technical debt/smells are **expected** in agile methodologies!
- **Technical Debt and Code Smells make the code hard to evolve.** It's difficult to add new features when you have technical debt or code smells that make simple changes complex to implement.
- Technical debt and code smells both refer to code that needs be restructured **before** changes can be safely made.

# Emergent code smells / tech. debt

```
public statement(): string {
    let totalAmount = 0;
    let result = "Rental Record for " + this.getName() + ":\n";
    for (const rental of this.rentals) {
        let rentalAmount = 0;
        switch (rental.getMovie().getPriceCode()) {
            case Movie.REGULAR:
                rentalAmount += 2;
                if (rental.getDaysRented() > 2) {
                    rentalAmount += (rental.getDaysRented() - 2) * 1.5;
                }
                break;
            case Movie.NEW_RELEASE:
                rentalAmount += rental.getDaysRented() * 3;
                break;
        }
        totalAmount += rentalAmount;
    }
    result += "Amount owed is " + totalAmount.toFixed(2) + ".\n";
    return result;
}
```

# Just one more thing!

```
public statement(): string {
    let totalAmount = 0;

    let result = "Rental Record for " + this.getName() + ":\n";
    for (const rental of this.rentals) {
        let rentalAmount = 0;
        // determine amounts for rental movie rented
        switch (rental.getMovie().getPriceCode()) {
            case Movie.REGULAR:
                rentalAmount += 2;
                if (rental.getDaysRented() > 2) {

# Emergent abstraction

Any time you are trying to make a change, and it is difficult because either...

- You have to make that change in **more than one place**.
- Changes (you can tell) will result in **merge conflicts** or changes to the same file as your teammate.
- The code is too **obfuscated** to be clearly understood.

...you run the risk of introducing bugs!

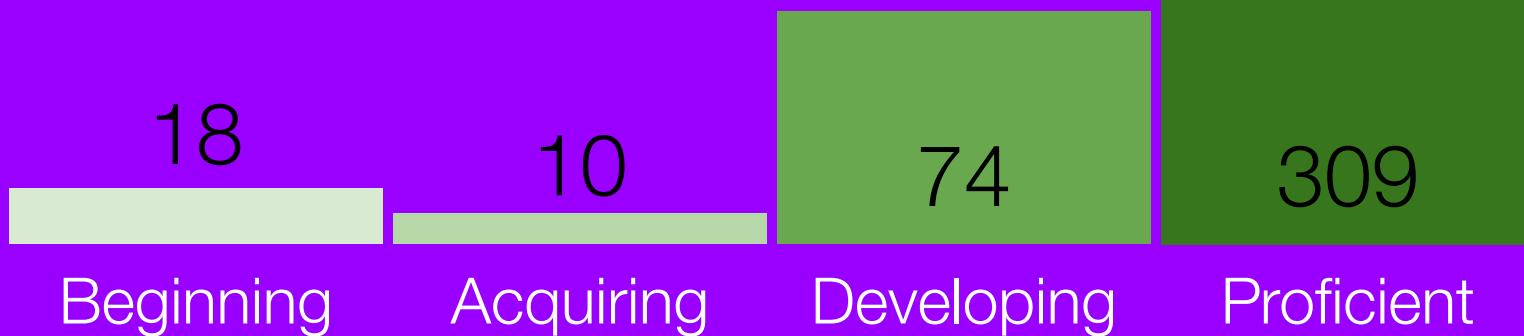

# Emergent abstraction

To avoid this: Refactor **before** you make the change by **introducing an abstraction** to either:

- **Solve** duplication/clone/scattering that causes the multiple change locations.
- **Reduce** tangling between the pieces of functionality by splitting them up.
- **Increase** code readability to make it more understandable.

# C1

- AutoTest latency < 15 mins whole deliv.
- 50% of teams at proficient by Tuesday.
- Classy should reflect your c1 bucket.
  - Your <highest,earliest> commit.
  - Issue will appear on your project repo soon.
- J1 due Friday @ 1800.
- C2 posted.
- #c2 and #check activated for C2.

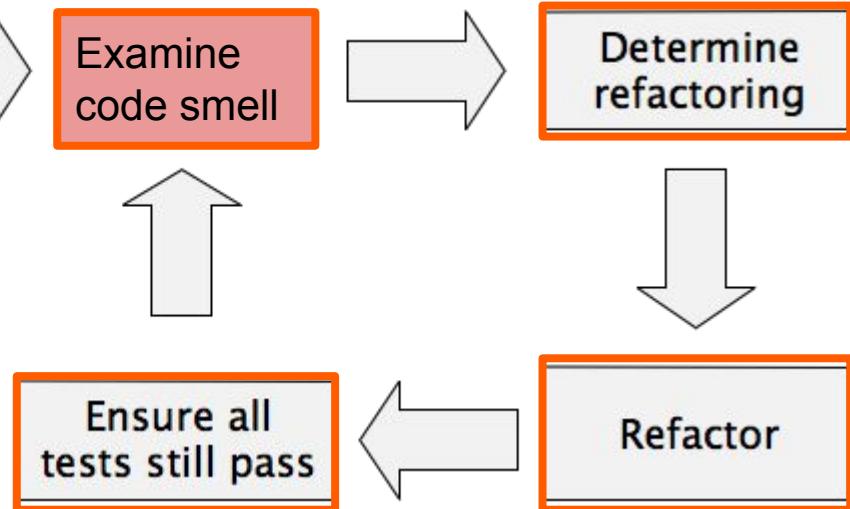

# How to Refactor?

Change is  
desired

Don't refactor...

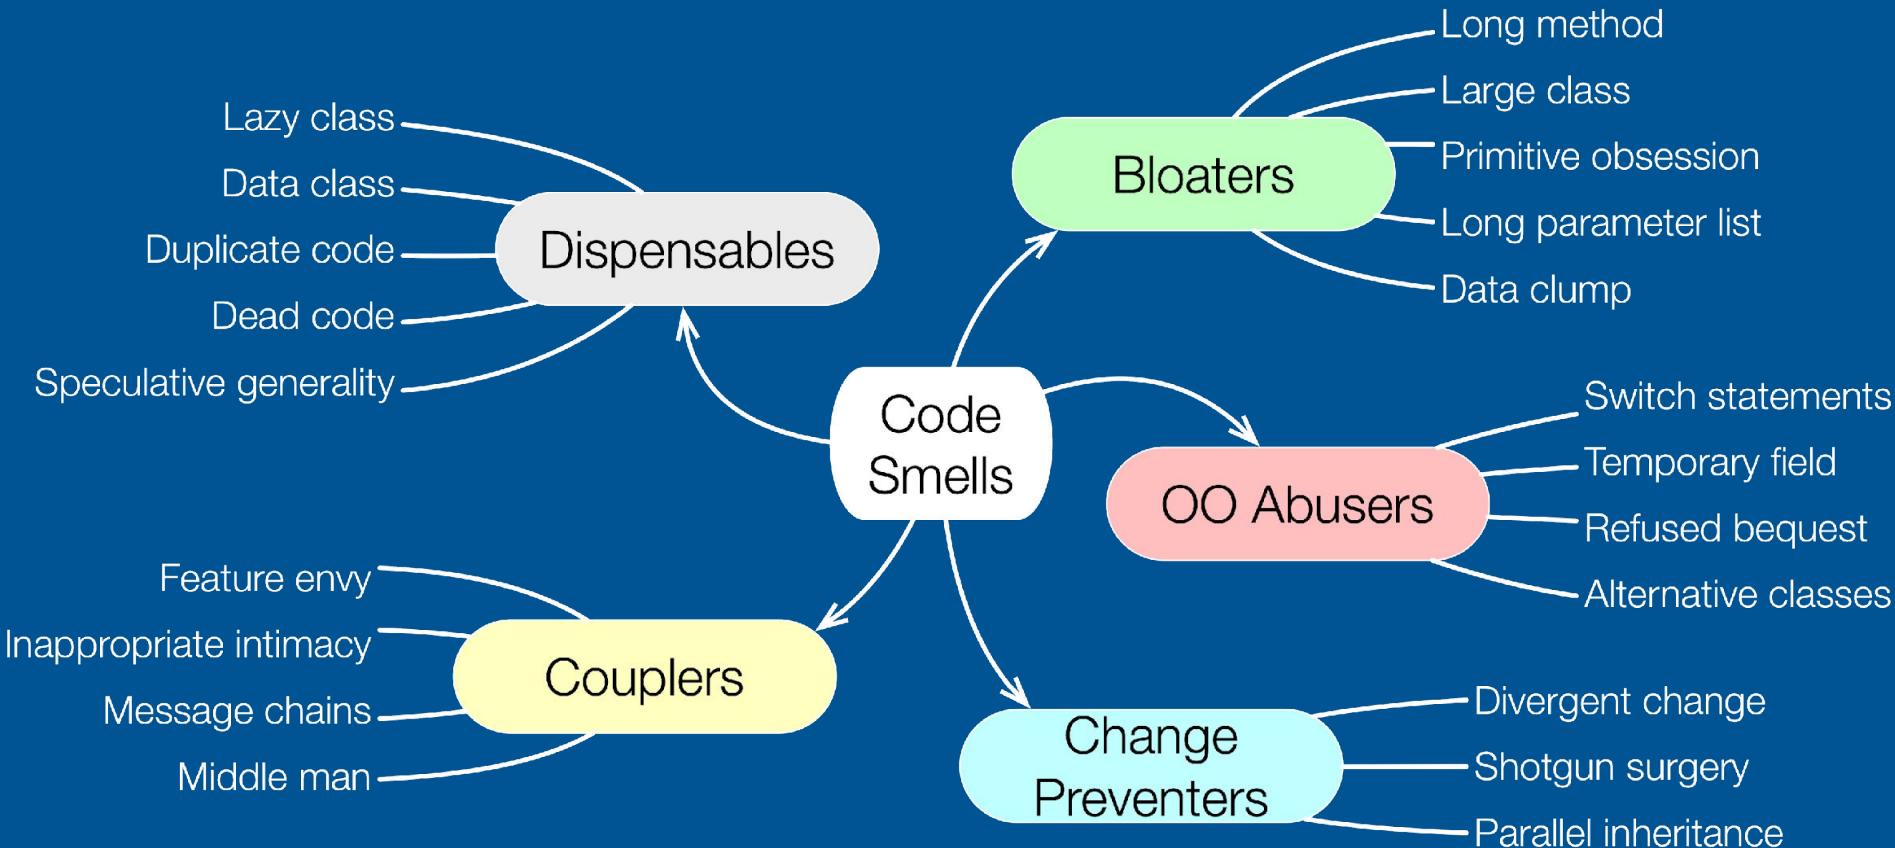

- When the tests are failing.
- When you should just rewrite the code.
- When you have impending deadlines.

1. Make sure all your tests pass.
2. Examine the code smell.
3. Determine how to refactor this code.
4. Apply the refactoring.
5. Run tests to make sure you didn't break anything.
6. Repeat until the smell is gone.

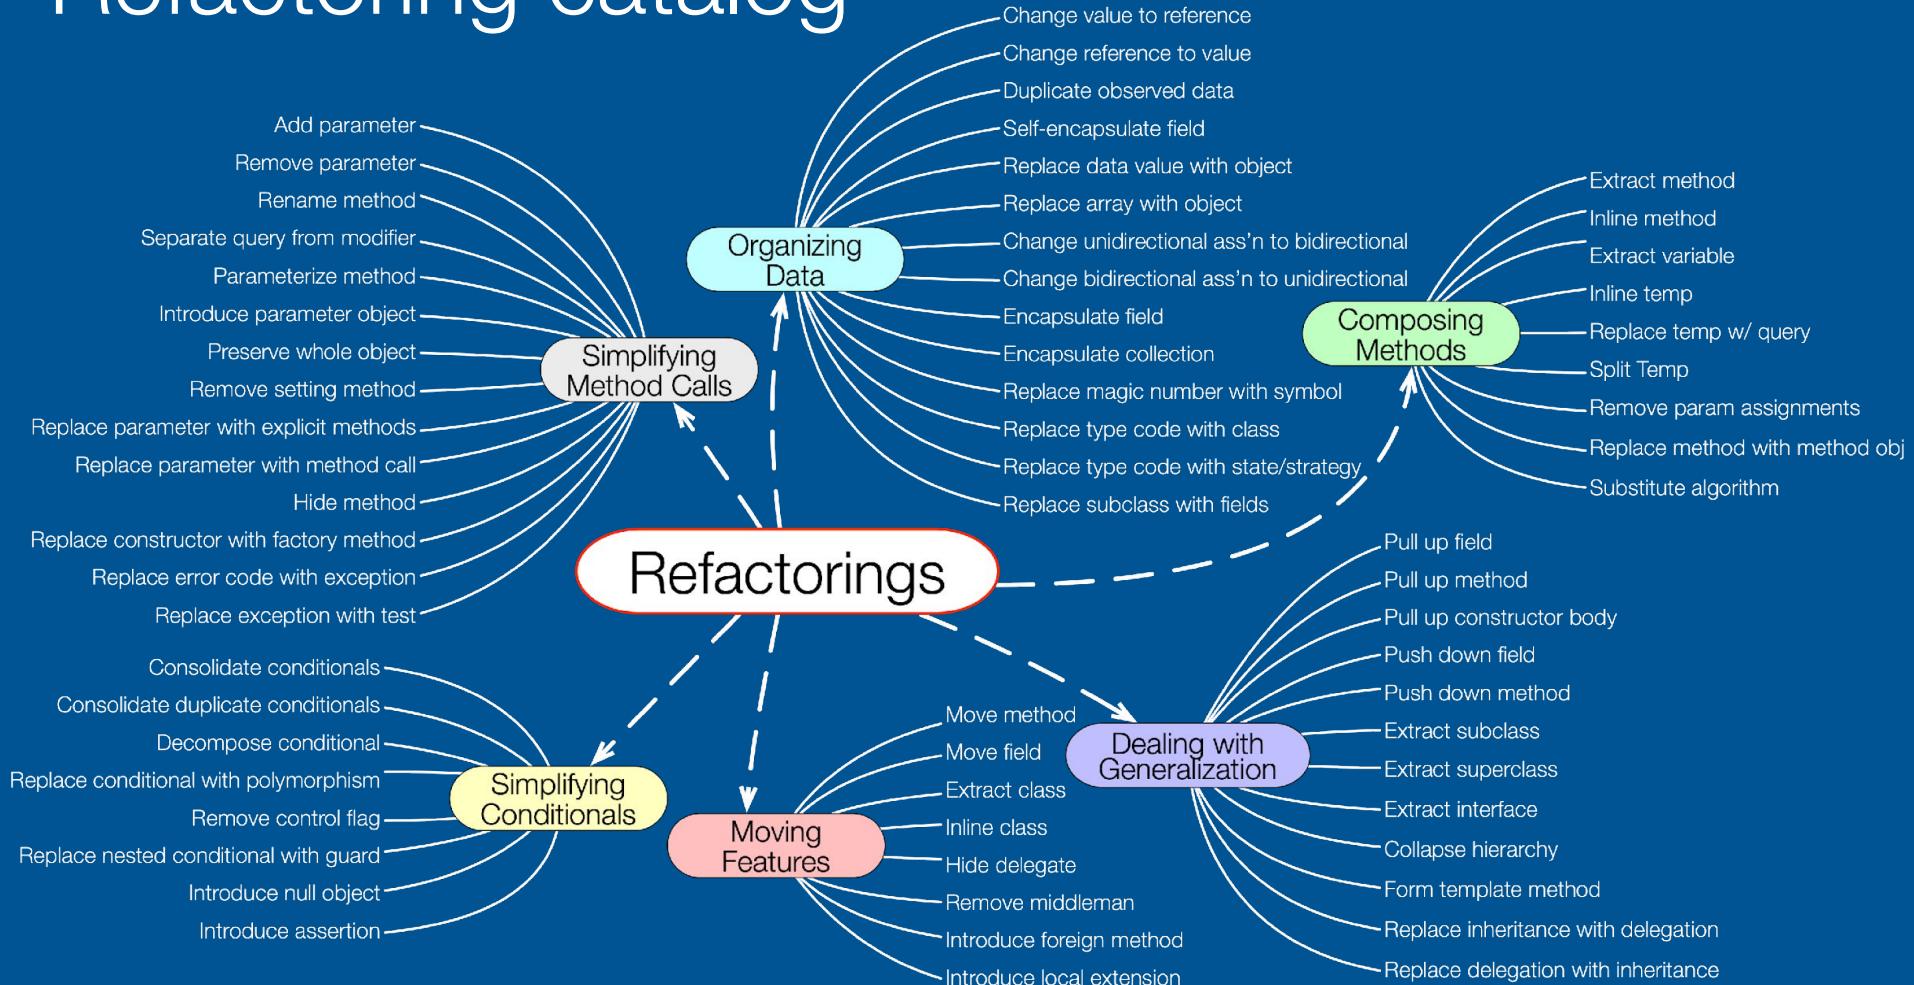

*"apply a refactoring"*

# How Do We Deal With Magic Numbers?

“Replace magic number with symbol” is a typical approach, but not the only one!

Any use of an actual number in the code.

```
potentialEnergy(mass: number, height: number): number {  
    return mass * 9.81 * height;  
}
```

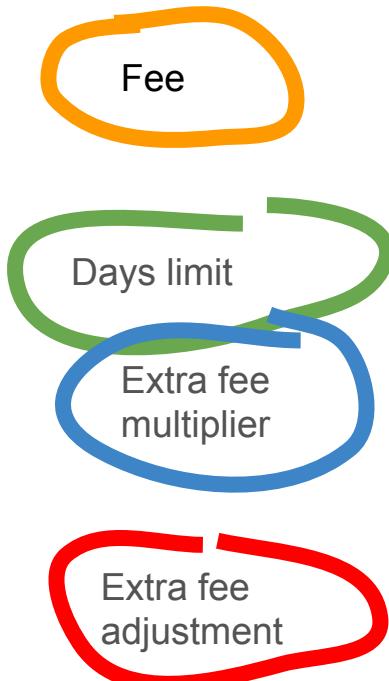

- a) You have to make that change in more than one place.
- b) Changes (you can tell) will result in merge conflicts.
- c) The code is too obfuscated to be clearly understood.

Maybe make this a constant and push your meanings into the type system.

```
potentialEnergy(mass: number, height: number): number {  
    const GRAVITATIONAL_CONSTANT = 9.81;  
    return mass * GRAVITATIONAL_CONSTANT * height;  
}
```

# Magic Number Proliferation

What to do?

```
//determine amount for each movie rented
switch (rental.getMovie().getPriceCode()){
    case "Regular":
        thisAmount = 2;
        if(rental.getDaysRented() > 2)
            thisAmount+=rental.getDaysRented();
        break;
    case "NEW RELEASE":
        thisAmount+=rental.getDaysRented()*3;
        break;
    case "CHILDRENS":
        thisAmount += 1.5;
        if (rental.getDaysRented() > 3)
            thisAmount+=(rental.getDaysRented()-3)*1.5;
}
```

# Transforming Magic Numbers

If these are not constants,  
we could make them variables.

```
//determine amount for each movie rented
switch (rental.getMovie().getPriceCode()){
    case "Regular":
        thisAmount+=2;
        if(rental.getDaysRented()>daysLimit)
            thisAmount+=rental.getFee();
        break;
    case "NEW RELEASE":
        thisAmount+=rental.getFee();
        break;
    case "CHILDRENS":
        thisAmount += 1.5;
        if (rental.getDaysRented()>daysLimit)
            thisAmount+=(rental.getFee()-
                rental.getFee()*extraFeeAdjustment);
}
```

```
let fee = 0;
let daysLimit = 0;
let extraFeeMultiplier = 0;
let extraFeeAdjustment = 0;
```

```
case "Regular":
    fee=2;
    daysLimit=2;
    thisAmount+=fee;
    if(rental.getDaysRented()>daysLimit)
        thisAmount+=rental.getDaysRented();
    break;
```

```
//determine amount for each movie rented
switch (rental.getMovie().getPriceCode()) {
    case "Regular":
        fee=2;
        daysLimit=2;
        thisAmount+=fee;
        if(rental.getDaysRented()>daysLimit)
            thisAmount+=rental.getDaysRented();
        break;
    case "NEW RELEASE":
        extraFeeMultiplier=3;
        thisAmount+=rental.getDaysRented()*extraFeeMultiplier;
        break;
    case "CHILDRENS":
        fee=1.5;
        daysLimit=3;
        extraFeeAdjustment=3;
        extraFeeMultiplier=1.5;
        thisAmount += fee;
        if (rental.getDaysRented()>daysLimit)
            thisAmount+=(rental.getDaysRented()-extraFeeAdjustment);
        break;
    case "SENIORS":
        fee=1;
        daysLimit=2;
        extraFeeAdjustment=2;
        thisAmount += fee;
        if (rental.getDaysRented()>daysLimit)
            thisAmount+=(rental.getDaysRented()-extraFeeAdjustment);
        break;
}
```

# Magic Numbers Removed

```
let fee = 0;
let daysLimit = 0;
let extraFeeMultiplier = 0;
let extraFeeAdjustment = 0;
```

```

# The Problem With Long Methods...

- Practically impossible to understand what's going on.
- Tests cannot help with fault localization because code blocks are not isolatable.
- Doesn't facilitate convenient extension by subtypes.

...

This method is too long. Could we extract this bit all the way to line 169 into a  
`splitPunctuation` sort of method?

```

# Method Design Aesthetics

All the same level  
of abstraction.

Differing levels of  
abstraction.

# Happens to shorter methods too!

Methods should do just one thing... at the *right* abstraction level.

```
private void selectAndPlayShapes() {
    shapesInColumn = drawing.getShapesAtColumn(playingColumn);

    for (Shape shape : lastColumnPlayed) {
        if (!shapesInColumn.contains(shape)) {
            shape.unselectAndStopPlaying();
        }
    }

    for (Shape shape : shapesInColumn) {
        if (!lastColumnPlayed.contains(shape)) {
            shape.selectAndPlay();
        }
    }
}
```

# Happens to shorter methods too!

Methods should do just one thing... at the *right* abstraction level.

```
private void selectAndPlayShapes() {
    shapesInColumn = drawing.getShapesAtColumn(playingColumn);
    stopLastStartPlayingNewColumn();
    for (Shape shape : lastColumnPlayed) {
        if (!shapesInColumn.contains(shape)) {
            shape.unselectAndStopPlaying();
        }
    }
    for (Shape shape : shapesInColumn) {
        if (!lastColumnPlayed.contains(shape)) {
            shape.selectAndStartPlaying();
        }
    }
}
```

The code illustrates a refactoring process. The original method call 'stopLastStartPlayingNewColumn()' is highlighted with a red box. This call is then expanded into two new methods: 'selectAndPlayShapes()' and 'stopPlayingLastColumnShapes()'. The 'selectAndPlayShapes()' method contains logic to handle shapes in the current column that were not in the previous column. The 'stopPlayingLastColumnShapes()' method handles shapes from the previous column that are no longer in the current column. A red curly brace on the left side groups the original method call and the first 'for' loop, indicating that both are being refactored together.

# Long parameter list

```
public pushCommit(  
    author: string,  
    commitId: string,  
    files: File[],  
    sha: string,  
    branch: string,  
    parentSHAs: [],  
    ts: Date) : Promise<boolean> {  
    // ...  
}
```

```
public pushCommit(commit: Commit) : Promise<boolean> {  
    // ...  
}
```

Hard to understand,  
annoying to use.

## CREATE PARAMETER OBJECT

- Replace the parameters with an object.

# Comment misuse

Good: Comment *technology*.

- Comment technology is *necessary* for specification and documentation (e.g. requires, modifies, effects).

Bad: Comments that *explain* code.

- Comments needed to explain code do not refer to specification or documentation. These are normally anti-patterns.
- Special exception for comments that describe \_why\_.

# Needing explanatory comments

“... comments often are used as a *deodorant*. It’s surprising how often you look at thickly commented code and notice that the *comments are there because the code is bad*.”

[Fowler & Beck, Refactoring]

“A good time to use a comment is when you don’t know what to do. In addition to describing what is going on, comments can indicate areas in which you aren’t sure. A comment is a good place to say why you did something. This kind of information helps future modifiers, especially forgetful ones.”

[Fowler]

# Needing explanatory comments

```
// convert to cents  
a = x * 100;  
// avg cents per customer  
avg = a / n;  
// add to list  
if (avgs < avg) { t.push(1) }
```

 cents = cost \* 100;  
centsPerCust = cents / totalCust;  
if (avgs < avg) { t.push(1) }

```

        }
    }
});
// *****

```

# Why are explanatory comments bad?

- People don't respect explanatory comments!
- You can change code, and not change the explanatory comments - this leads to documentation drift.
- Explanatory comments don't necessarily move with code!
- You could accidentally:
  - Copy and paste code but forget an explanatory comment.
  - Add new code between the explanatory comment and the implementation it refers to.
  - Make a change that makes the comment misleading.

Comments often signal clusters of behaviour - and indicate a method is doing more than it should.

# Fixing explanatory comments

- Extract method and give that method a useful name.
- Named elements *become* the documentation.
- People respect names: people generally will *not willingly* change the contract of a class/method/field.
- Documentation “envelopes” move with code: when you instantiate a class, reference a field, or call a method you implicitly access the documentation through its name.

    }
    // generate footer
    result += "Amount owed is " + totalAmount.toFixed(2) + ".\n";
    result += "You earned " + frequentRenterPoints.toFixed(0) + " frequent renter points.";

    return result;
}
```

```
private simplifiedStatement(): string {
    let totalAmount = 0;
    let statement = this.getHeader();
    for (const rental of this.rentals) {
        const rentalAmount = this.getRentalAmount(rental);
        this.addRenterPoints(rental);
        this.addBonuses(rental);
        statement += this.generateStatementLine(rental, rentalAmount);
        totalAmount += rentalAmount;
    }
    statement += this.getFooter(totalAmount);
    return statement;
}
```

```
private simplifiedStatement(): string {
    let statement = this.getHeader();
    statement += this.getStatementRows();
    const totalAmount = this.getTotalAmount();
    statement += this.getFooter(totalAmount);
    return statement;
}
```

# Switch on type

A conditional varying behaviour based on an object's type:

**Class Bird:**

```
public getSpeed(obj:BirdContainer): number {
    switch (obj.kind) {
        case Bird.EUROPEAN:
            return this.getBaseSpeed();
        case Bird.AFRICAN:
            return this.getBaseSpeed() - this.getLoad() * this.coconutCount;
        case Bird.NORWEGIAN_BLUE:
            return (this.isNailed) ? 0 : this.getBaseSpeed();
    }
    throw new Error("Unknown kind of bird");
```

# Refactoring: Replace conditional with polymorphism

```
public getSpeed(obj:any): number {  
    switch (obj.kind) {  
        case Bird.EUROPEAN:  
            return this.getBaseSpeed();  
        case Bird.AFRICAN:  
            return this.getBaseSpeed() - this.getLoad() * this.coconutCount;  
        case Bird.NORWEGIAN_BLUE:  
            return (this.isNailed) ? 0 : this.getBaseSpeed();  
    }  
    throw new Error("Unknown kind of bird");  
}
```

Bird class

Each method gets the contents of the case body

Each case gets its own class

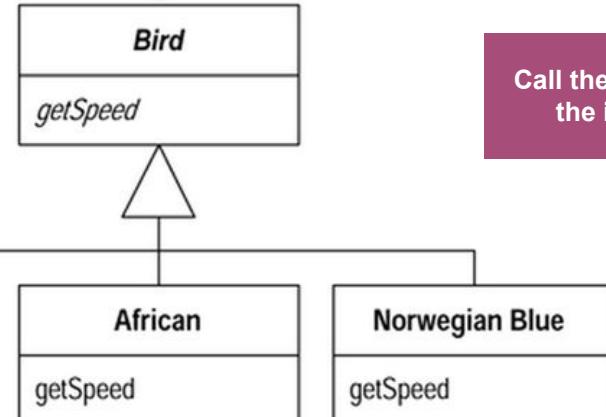

Each class gets its own version of the method

```
return getBaseSpeed();
```

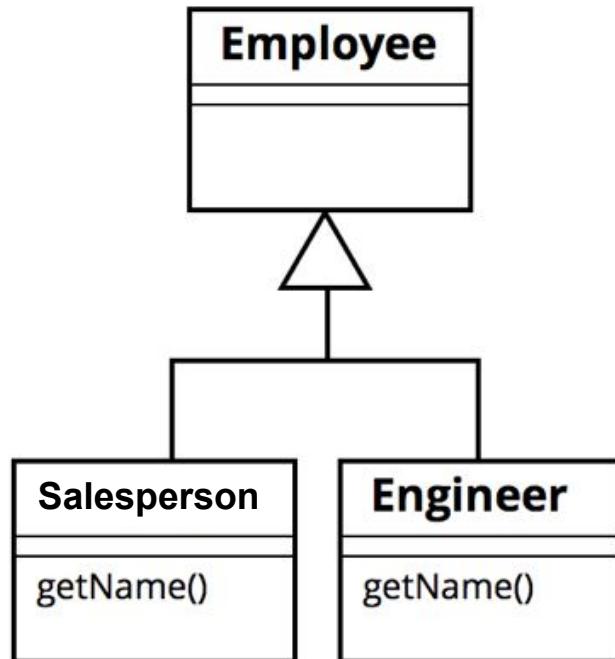

Instantiate the subtype

```
private calcProperties(): void {  
    const bird: Bird = new African();  
    const speed = bird.getSpeed();  
    // ... use speed  
}
```

Call the method on the instance

# Identical methods in two classes

Pull up Method Refactoring:

- 1) Create method in superclass.
- 2) Remove from subclasses.

# Almost identical methods in two classes

```
class VerboseReport extends CollectionsReport {  
    public printReport(): void {  
        console.log("==Start==");  
        console.log("We are so sorry to tell you...");  
        console.log("Here's the thing");  
        console.log("We might need that money back");  
        console.log("I know, we're sorry");  
        console.log("==End==");  
    }  
}
```

```
abstract class CollectionsReport {  
    public abstract printReport(): void;  
}
```

```
class ConciseReport extends CollectionsReport {  
    public printReport(): void {  
        console.log("==Start==");  
        console.log("Give us our money");  
        console.log("==End==");  
    }  
}
```

## Pull up Method Refactoring:

- 1) Create method in superclass.
- 2) Remove from subclasses.
- 3) Add extension points in subclasses.

# 1) Identify what is common and unique

```
class VerboseReport extends CollectionsReport {  
    public printReport(): void {  
        console.log("==Start==");  
        console.log("We are so sorry to tell you...");  
        console.log("Here's the thing");  
        console.log("We might need that money back");  
        console.log("I know, we're sorry");  
        console.log("==End==");  
    }  
}
```

```
abstract class CollectionsReport {  
    public abstract printReport(): void;  
}
```

Unique to this class

Unique to this class

```
class ConciseReport extends CollectionsReport {  
    public printReport(): void {  
        console.log("==Start==");  
        console.log("Give us our money");  
        console.log("==End==");  
    }  
}
```

## 2) Pull up duplicate behaviour

```
abstract class CollectionsReport {  
    public abstract printReport(): void;  
}
```

```
class VerboseReport extends CollectionsReport {  
    public printReport(): void {  
        console.log("==Start==");  
        console.log("We are so sorry to tell you...");  
        console.log("Here's the thing");  
        console.log("We might need that money back");  
        console.log("I know, we're sorry");  
        console.log("==End==");  
    }  
}
```

```
class ConciseReport extends CollectionsReport {  
    public printReport(): void {  
        console.log("==Start==");  
        console.log("Give us our money");  
        console.log("==End==");  
    }  
}
```

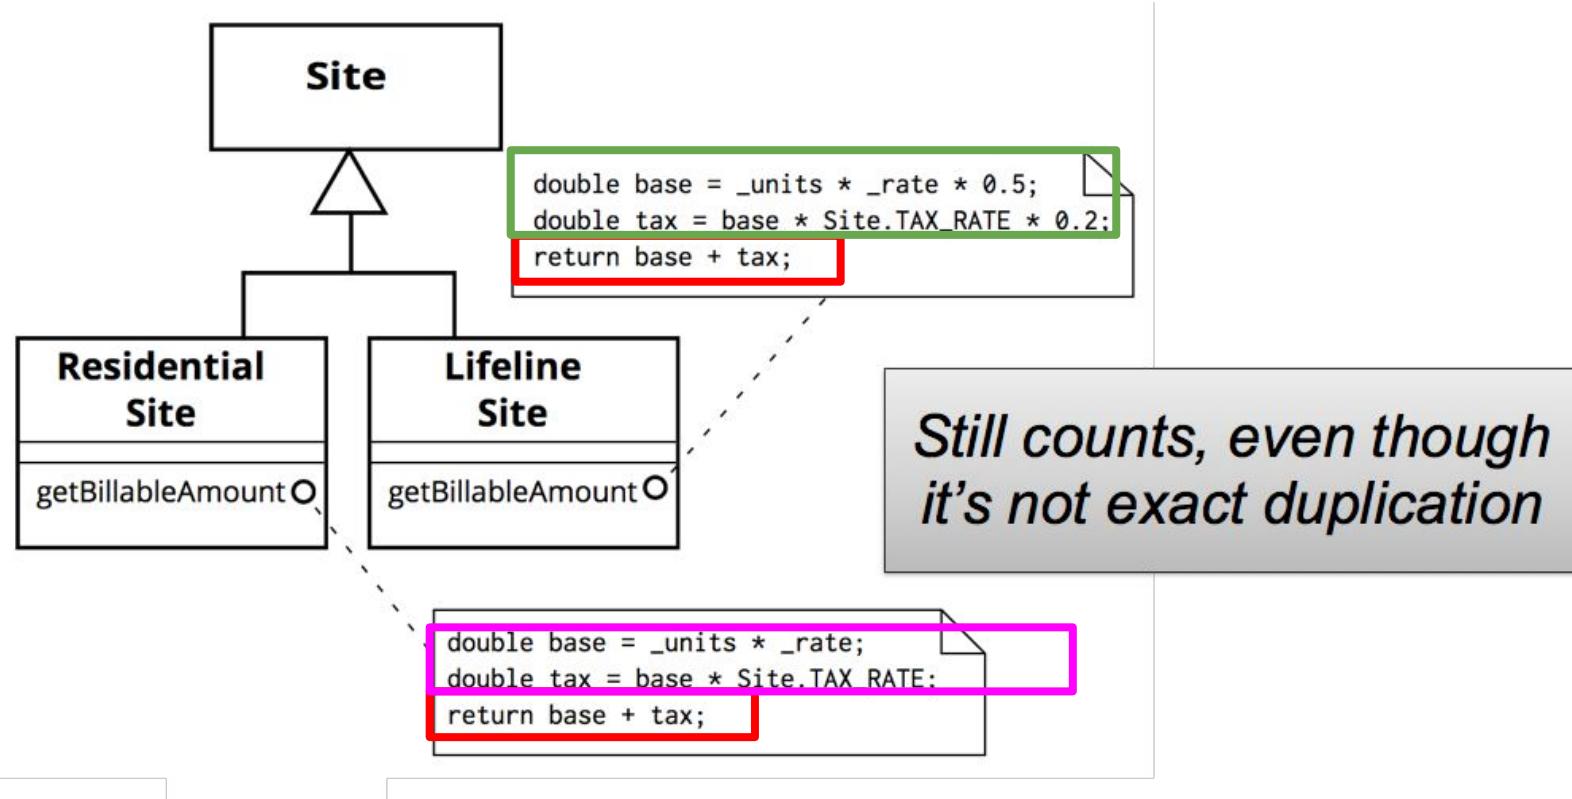

# 3) Make an abstract method that calls unique functionality.

```
class VerboseReport extends CollectionsReport {  
    public printContents(): void {  
        console.log("We are so sorry to tell you...");  
        console.log("Here's the thing");  
        console.log("We might need that money back");  
        console.log("I know, we're sorry");  
    }  
}
```

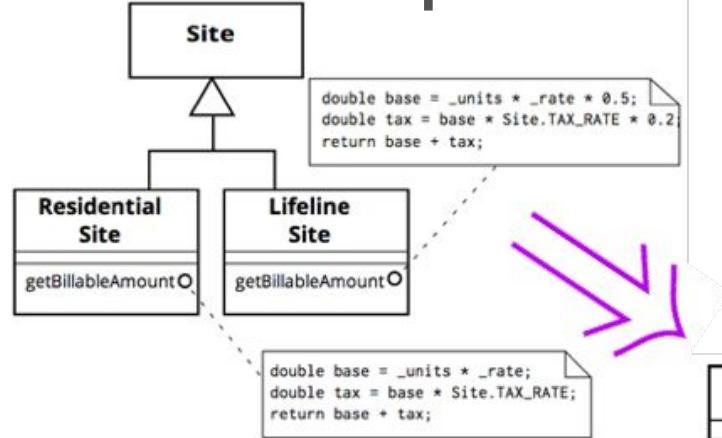

```
abstract class CollectionsReport {  
    public printReport(): void {  
        console.log("==Start==");  
        this.printContents();  
        console.log("==End==");  
    }  
    public abstract printContents(): void;  
}
```

```
class ConciseReport extends CollectionsReport {  
    public printContents(): void {  
        console.log("Give us our money");  
    }  
}
```

# Almost Duplicate Code (Again)

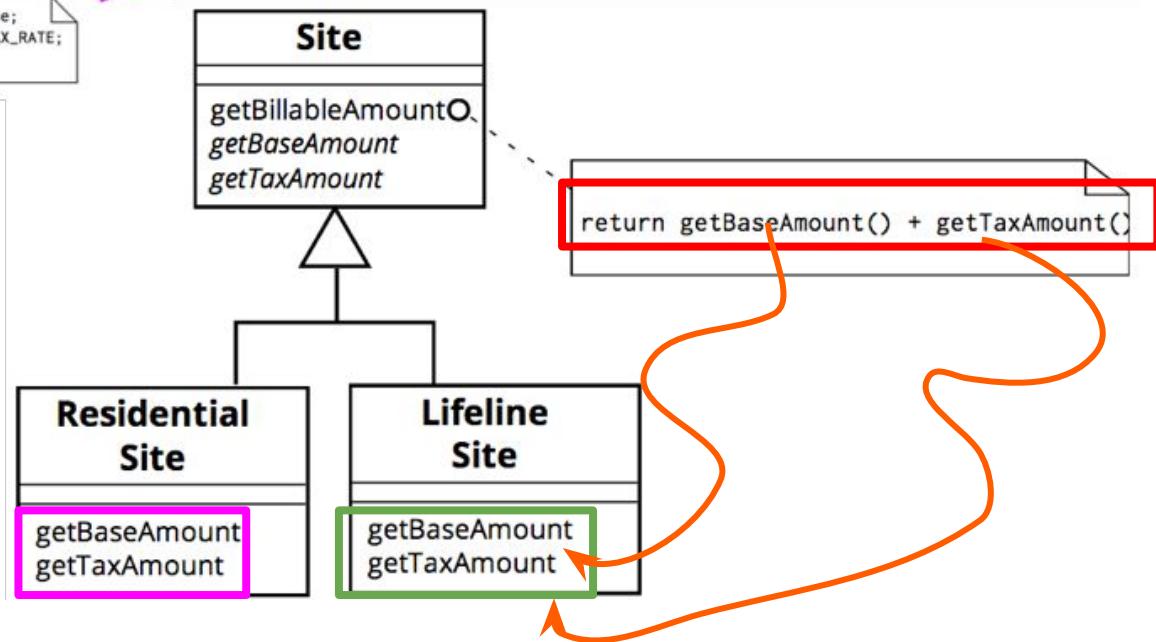

# Create Template Method

## Template Method Refactoring:

- 1) Pull up the duplicate code (or duplicated logic) into the super method.
- 2) The super method calls an abstract helper method that inserts the contents.
- 3) The subclasses provide the implementations for the contents method.

# Feature Envy (Behaviour in Wrong Place)

When you find yourself wishing you had access to lots of fields from another class, the method you're implementing should probably live in that class.

```
class Cat {  
    private fido = new Dog();  
    public chaseDog() {  
        this.fido.tail.wag();  
        this.fido.mouth.smile(); ←  
        // ... etc  
    }  
}
```

Law of Demeter: Too many dereferences mean the method is probably in the wrong spot.

Why is Cat telling Dog how to behave? Objects should define their own behaviour.

```
this.db.students[sNum].courses['cs310'].getC2().push();
```

# Experiential Code Smell Symptoms (Issues you notice while changing code)

The issues that we have seen up to this point are all *static*, they can be readily identified just by looking at the code.

In reality, code smells are identified *experientially*: as you try to *change* or understand code.

Two experiential symptoms that point to more elusive (and problematic) code smells are **divergent changes** and **shotgun surgery**.

These smells often highlight the need for a new class to abstract the tangled or scattered design elements.

- a) You have to make a change in more than one location.
- b) *Changes (you can tell) will result in development collisions.*
- c) *The code is too obfuscated to be clearly understood.*

# Divergent Changes

Divergent changes occur when one class is commonly changed in different ways for different reasons.

Any change to handle a variation should change only a single class, and that class should capture the unique variation.

## **InvestmentAccount**

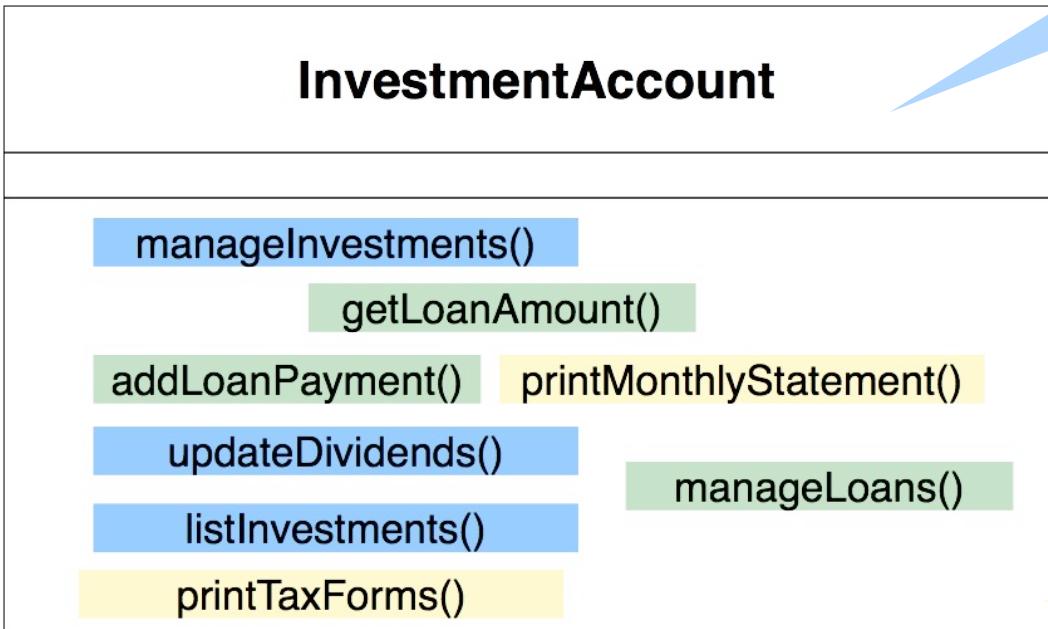

**manageInvestments()**  
**getLoanAmount()**

**addLoanPayment()**    **printMonthlyStatement()**  
**updateDividends()**                                    **manageLoans()**  
**listInvestments()**  
**printTaxForms()**

If you look at a class and say, "Well, I will have to change these three methods every time I get a new database connection; I have to change these four methods every time there is a new financial instrument," you likely have a situation in which two classes are better than one. That way each object is changed only as a result of one kind of change. Of course, you often discover this only after you've added a few databases or financial instruments.

# Divergent Changes

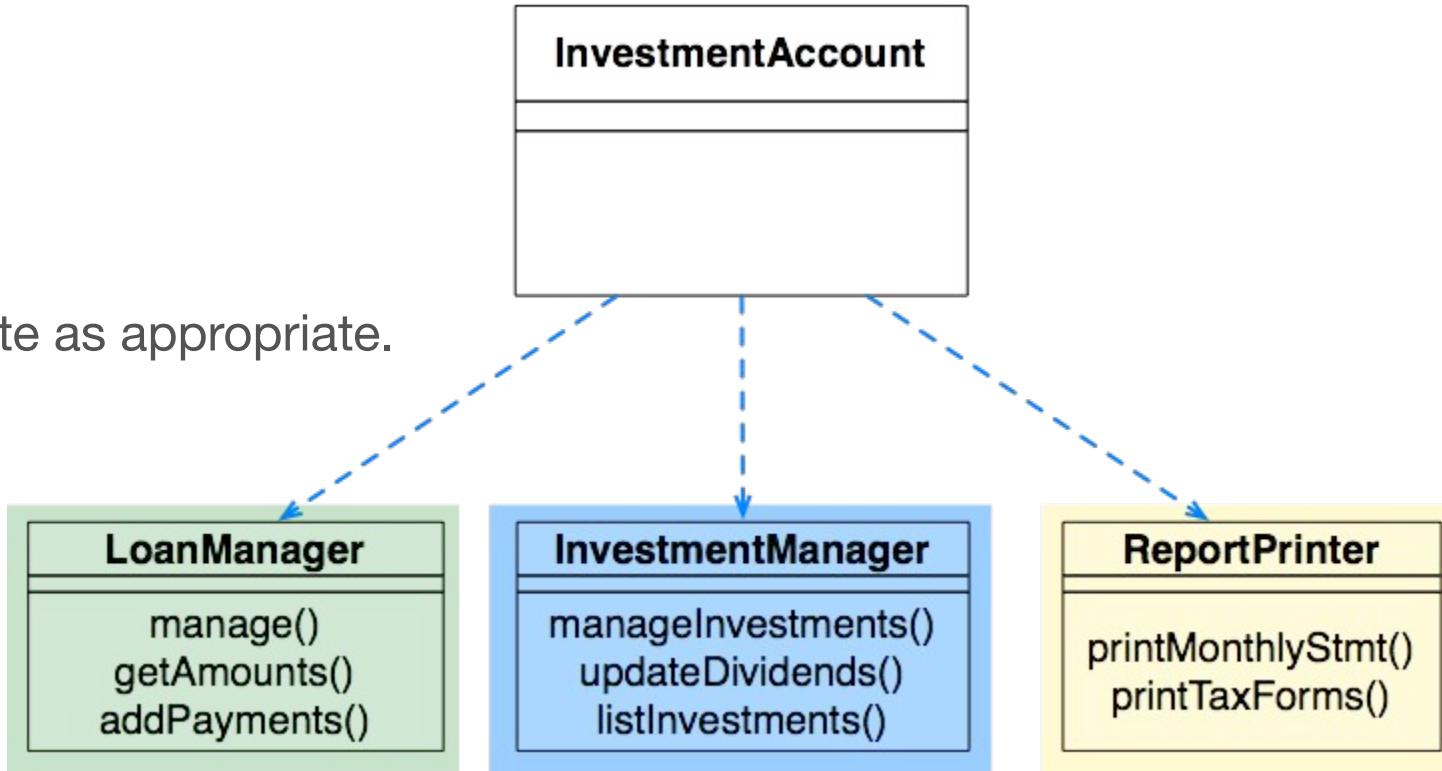

Will need to change whenever the investments implementation is changed.

Will need to change whenever the loans implementation is changed.

Will need to change every time the printing implementation is changed.

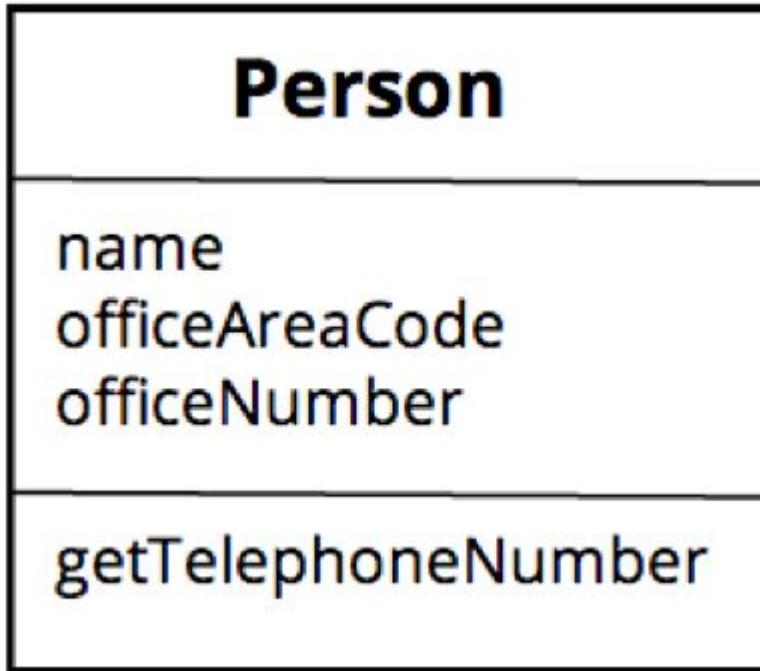

# Extract Behaviours Into Their Own Classes

Delegate as appropriate.

# Symptom: Divergent Changes

## Code smell: One Class is Actually Two

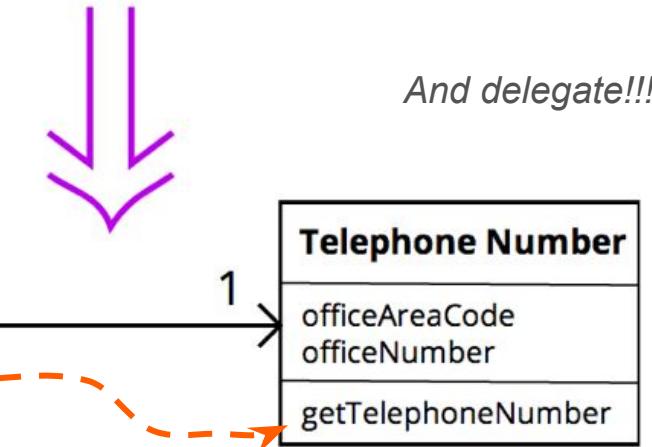

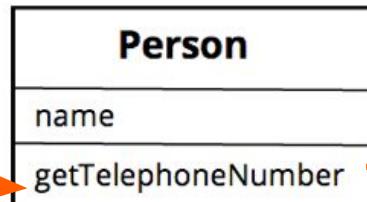

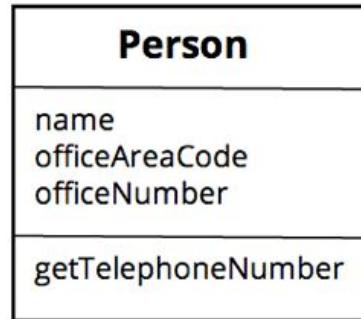

There is more than one field related to the telephone number, which gives it more weight. There might be additional methods supporting the phone number.

# Code Smell: One Class is Actually Two

## Refactoring: Extract Class

```
Person p = new Person()  
p.getTelephoneNumber()
```

# Code Smell: One Class is Actually Two

## Refactoring: Extract Class

Seems to be about  
billing, not about  
being a customer!

Customer

- m printStatement(): String
- m getTotalAmount(double): double
- m addBonuses(Rental): void
- m getStatementLine(double): String
- m getTotalAmount(double, double): double
- m addRenterPoints(): void
- m rentMovie(Movie, int): void
- f ◊ rentals: ArrayList<Rental> = new ArrayList<Rental>()
- f frequentRenterPoints: int = 0

# Code Smell: One Class is Actually Two

## Refactoring: Extract Class

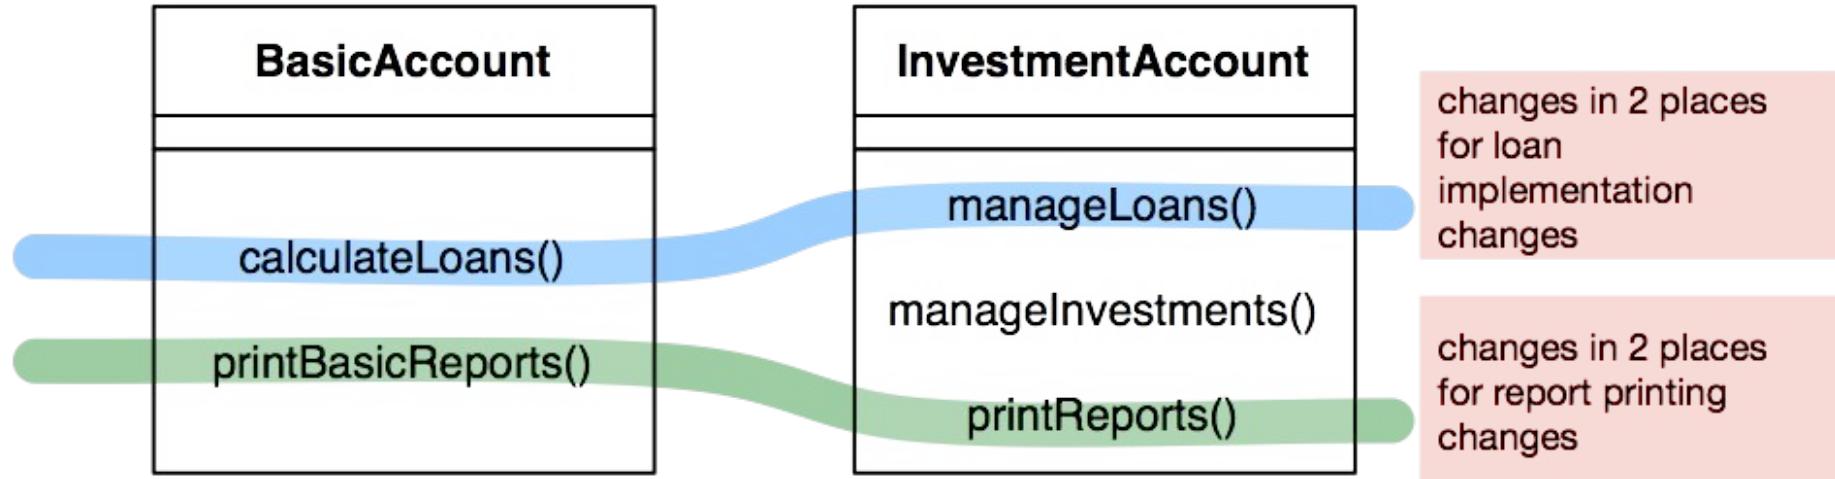

```
▼ c Invoice
  m b Invoice(Customer)
  m g printStatement(): String
  m o getTotalAmount(): double
  m o addBonuses(Rental): void
  m o getStatementLine(double): String
  m o getBillingAmount(double, double): double
  f o customer: Customer
```

```
// customer.printStatement(); →
const invoice = new Invoice(customer);
invoice.printStatement();
```

```
▼ c Customer
  m g addRenterPoints(): void
  m g addRenterPoints(int): void
  m g rentMovie(Movie, int): void
  m g getRentals(): ArrayList<Rental>
  m g getRenterPoints(): int
  f o rentals: ArrayList<Rental> = new ArrayList<
  f o frequentRenterPoints: int = 0
```

The approach here is typically to make the class, then copy the methods over, then get them to compile, then alter the invocation so the new methods are being called, and run tests. Only then do you delete the old methods.

# Shotgun Surgery

You whiff this when every time you make a kind of change you have to make lots of little changes in lots of different places. When changes are scattered they're hard to find and easy to miss.

Catchy synonym for  
Delocalized or  
Scattered change.

# Divergent Changes and Shotgun Surgery

Divergent change is one class that suffers many kinds of changes, and shotgun surgery is one change that alters many classes. Either way you want to arrange things so that, ideally, there is a one-to-one link between common changes and classes.

[Fields, Harvie, & Fowler]

# Underpinning Principle of Design

Makes an important statement on OO design:

That classes not *just* be considered in terms of their apparent responsibility, but must also be centered around their empirically observed relevance!

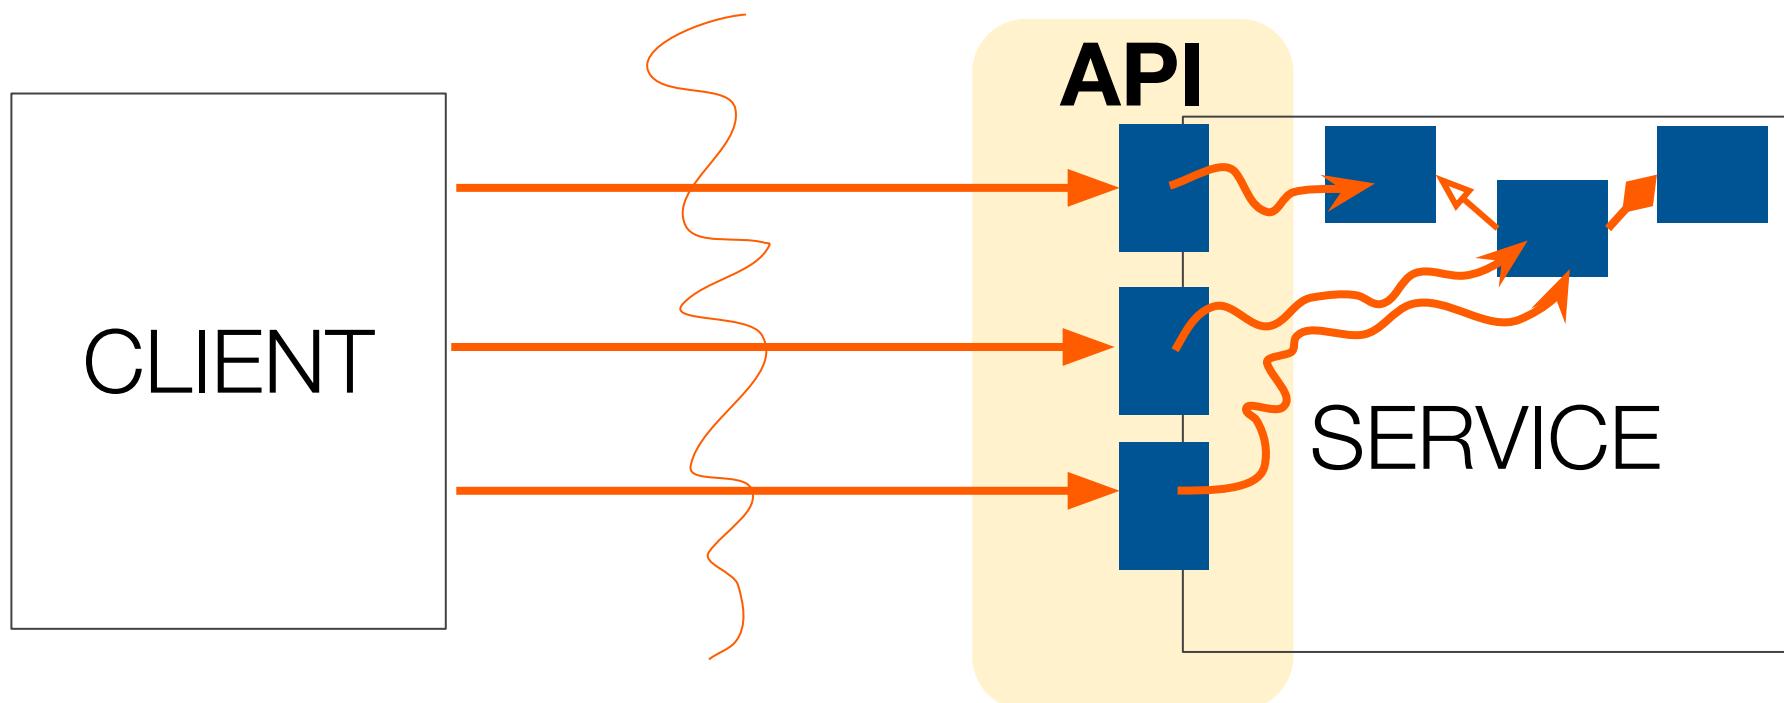

Systems should be decomposed to support evolution.

REST

# Examinable Skills

- Spot non-RESTful qualities in a service: endpoints and semantics (using client side context to compute a “next” link, for instance).
- Structure a RESTful service given a description of the service
- Provide appropriate responses for each of the URIs in a RESTful service.
- Given a client-side user story, describe what the client side pseudo code would look like (what request it would send, would it be in a loop or an individual request, etc.).
- Relate RESTful qualities to the other design principles: the concept of localisation of reasoning and change.
- Discuss how RESTful services can use versioning to evolve their APIs.

# Revisiting APIs

# RESTful Design Principles

We were taking a journey through Object Oriented design, but we're going to briefly zoom out to inter-component design!

Underpinning Principles:

- 1) Localisation of reasoning.
- 2) Reduction in the propagation of change.

# Why has REST become so pervasive?

- In *No Silver Bullet*, Fred Brooks states that: “The best way to address the complexity of software is to not build it at all.”
  - Several long-sought NSB solutions favour reuse:
    - As a means to reduce complexity.
    - As a means to improve productivity.
    - As a means to increase reliability.
    - As a means to encourage / enable reuse.

# Reuse in practice

- New features are added by “dropping in” components:
  - Accounts for 53% of reuse at NASA. [Selby 2005]
- Domain-specific component markets:
  - Populated by carefully created reusable components.
  - This is harder than it sounds.
- Three main impediments:
  - High up-front cost. [Gaffney 1992, ICSE]
  - Architectural mismatch. [Garlan *et. al.* 1995, IEEE Software]
  - Library scaling problem. [Biggerstaff 1994, ICSR]

# Up front costs

- Budgets are drawn up annually
  - Heavy emphasis on the current quarter
- Reusable software is:
  - ~Twice as expensive [Gaffney 1992, ICSE]
  - ~Three times as expensive [Brooks 1975]
- Requires careful forethought to determine what software *will* be reused and whether any savings outweigh extra costs
- What is the benefit to the customer?

# Architectural Mismatch

- Even reusable code makes some assumptions about *how* it should be reused; these assumptions are often implicit
  - Explicit assumptions are often easy to identify:
    - Programming language
    - Libraries & frameworks
  - Implicit assumptions are harder to spot:
    - Topology assumptions
    - Protocols of use
- Implicit assumptions are often not documented because the original developer may not have considered them constraints.

# Library Scaling

- Two extremes:
  - Large, feature-laden, components.
  - Small, simple, components.
- Large components are hard to adapt.
- Small components have complex cost/benefit implications.

# Let's Look at an Example

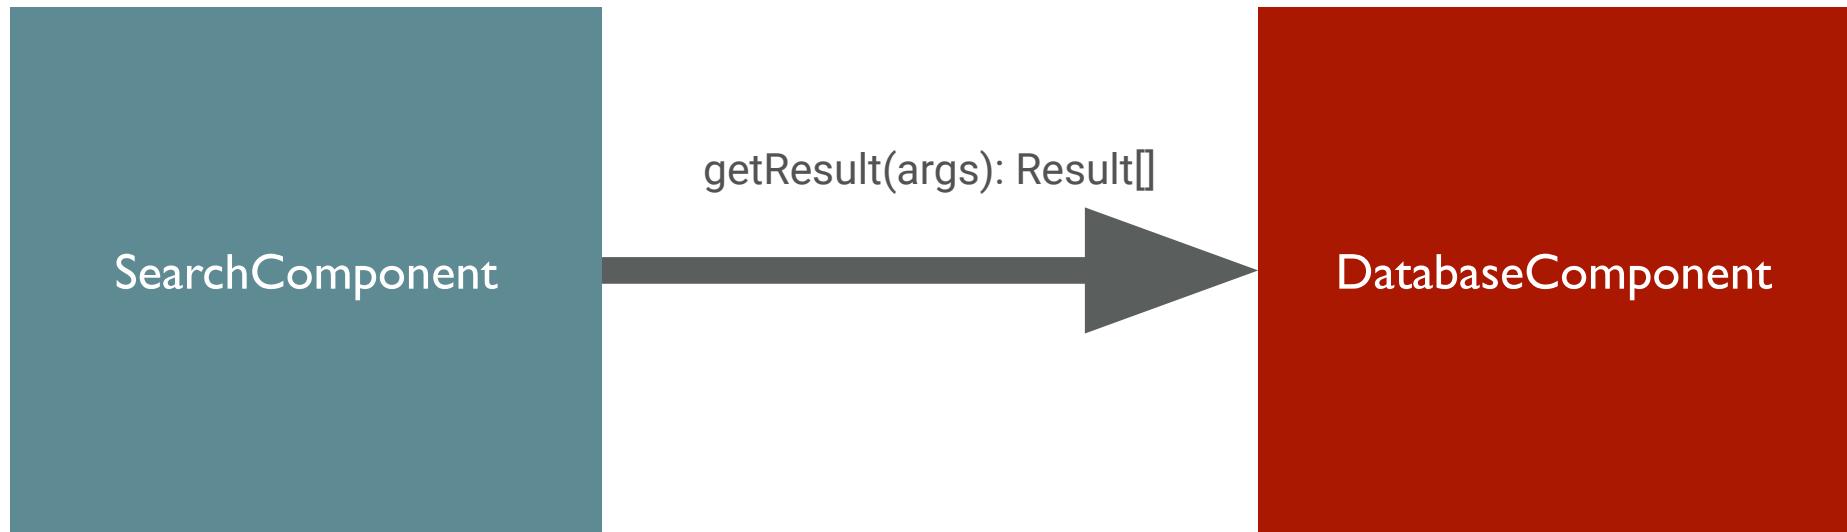

## CanaFind:

- **Finders:** As someone who found something in a public place, I would like to be able to upload a photo of that thing, so their owner can learn that it has been found.
- **Searcher:** As someone who lost something in a public space, I would like to be able to look at a location on a map and see whether anything was found there, so I can see if someone has found what I have lost.

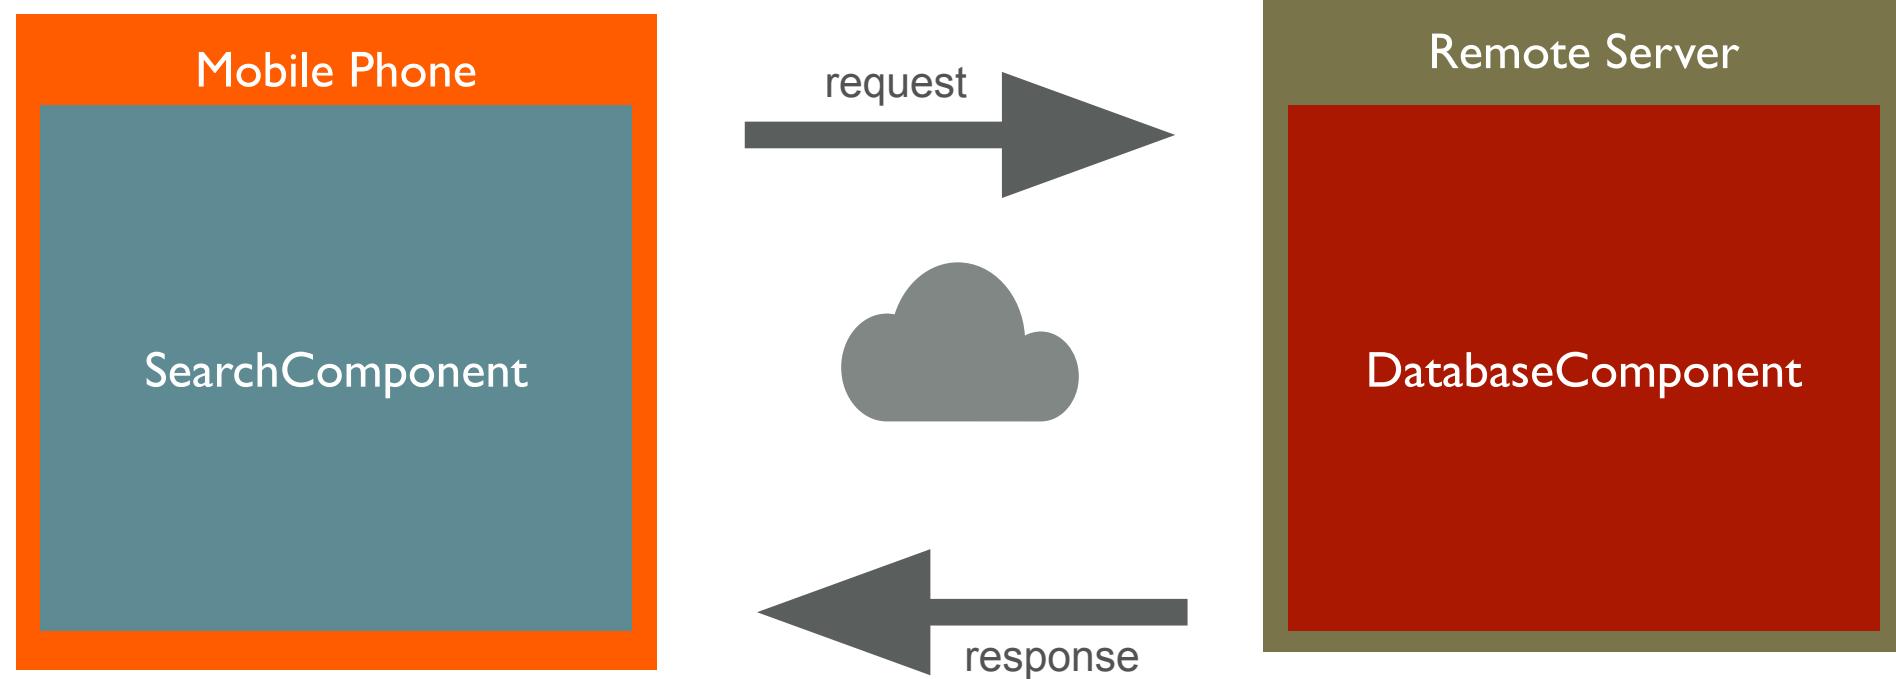

(Yes, this assumes no one will move anything.)

(It's not a perfect system.)

# What is This All About?

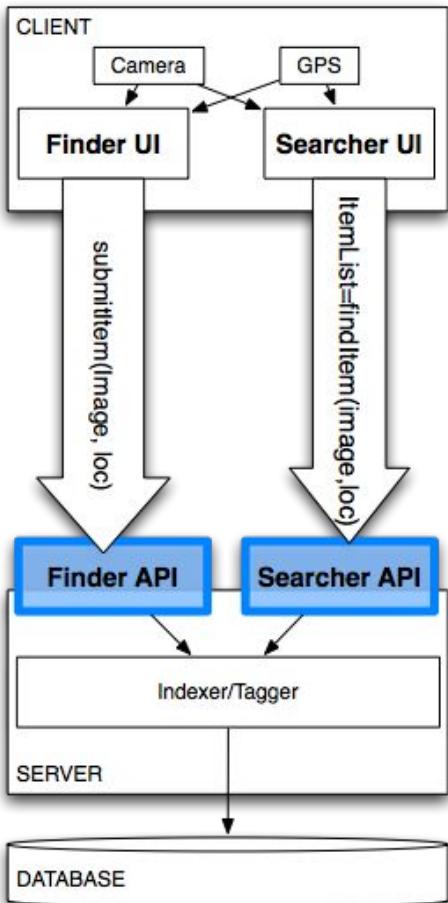

# RPC

# An “RPC” Approach

Delocalization of changes!!!!  
(Server changes propagate to client!)

- This approach involves **Remote Procedure Calls**, and a lot of integration between client and server.
- Note that the calls are specialised ‘verbs’ (`submitItem(...)`, `findItem(...)`).
- **Pro:** Simple to program, behaves like local calls.
- **Con:** The protocol must be pre-defined. The client and the server must agree on methods/data types.
- This is the approach used in the Simple Object Access Protocol (SOAP) ...which we will not cover.
- RPC is covered in much more detail in CPSC 416.

# Another Way: REST

- REpresentational
- State
- Transfer

# RESTful Interfaces

“... the web is an existence proof of a massively scalable **distributed system** that works really well, and we can take ideas from that to **build integrated systems** more easily.” – Martin Fowler

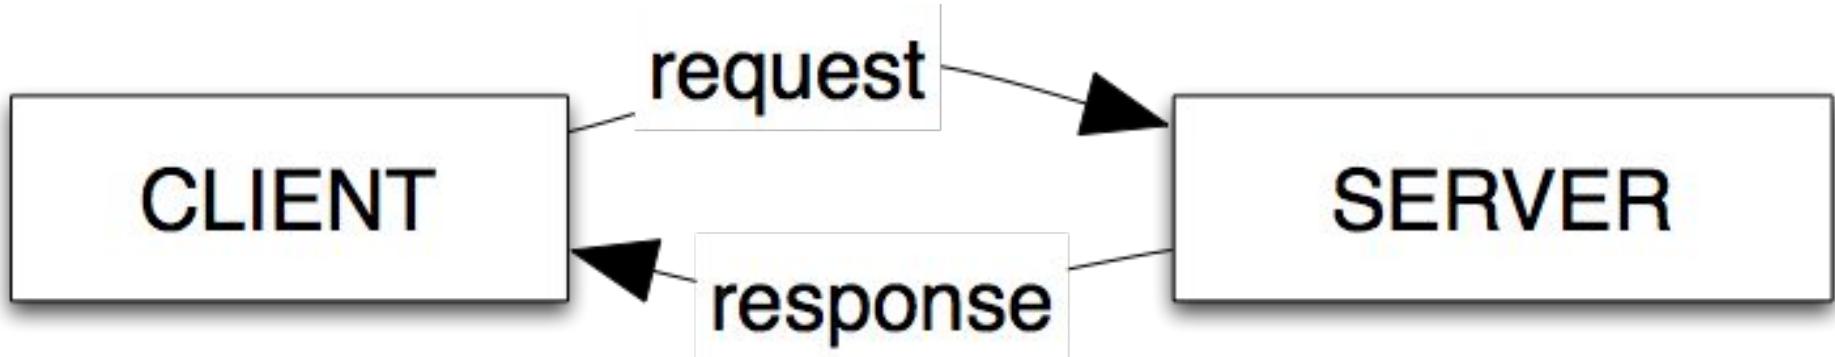

"Representational State Transfer is intended to evoke an image of how a **well-designed** Web application behaves: a network of web pages (a virtual state-machine), where the user progresses through an application by selecting links (**state transitions**), resulting in the next page (representing the **next state** of the application) being transferred to the user and rendered for their use." - Roy Fielding

[<http://roy.gbiv.com/untangled/2008/rest-apis-must-be-hypertext-driven>]

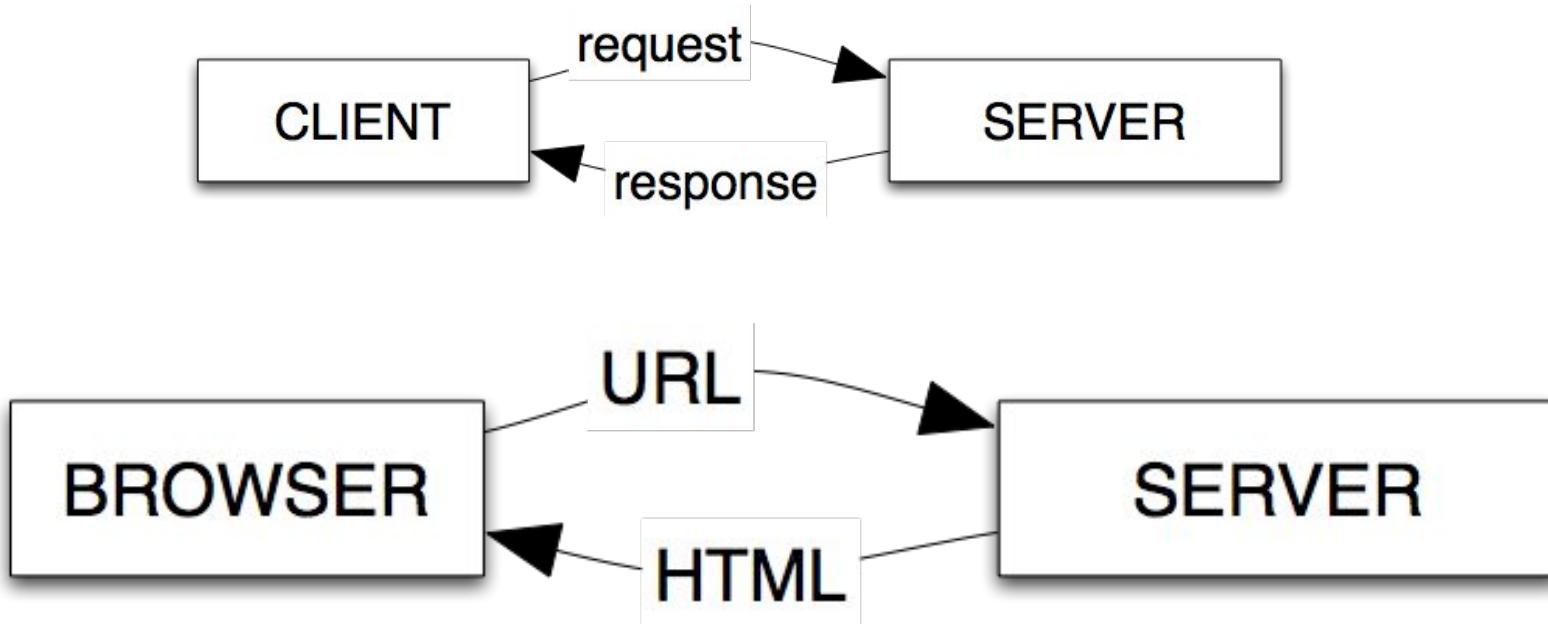

Roy Fielding interview: [<https://www.youtube.com/watch?v=w5j2KwzzB-0>]

# REST: Basics

# If Your Client is a Browser

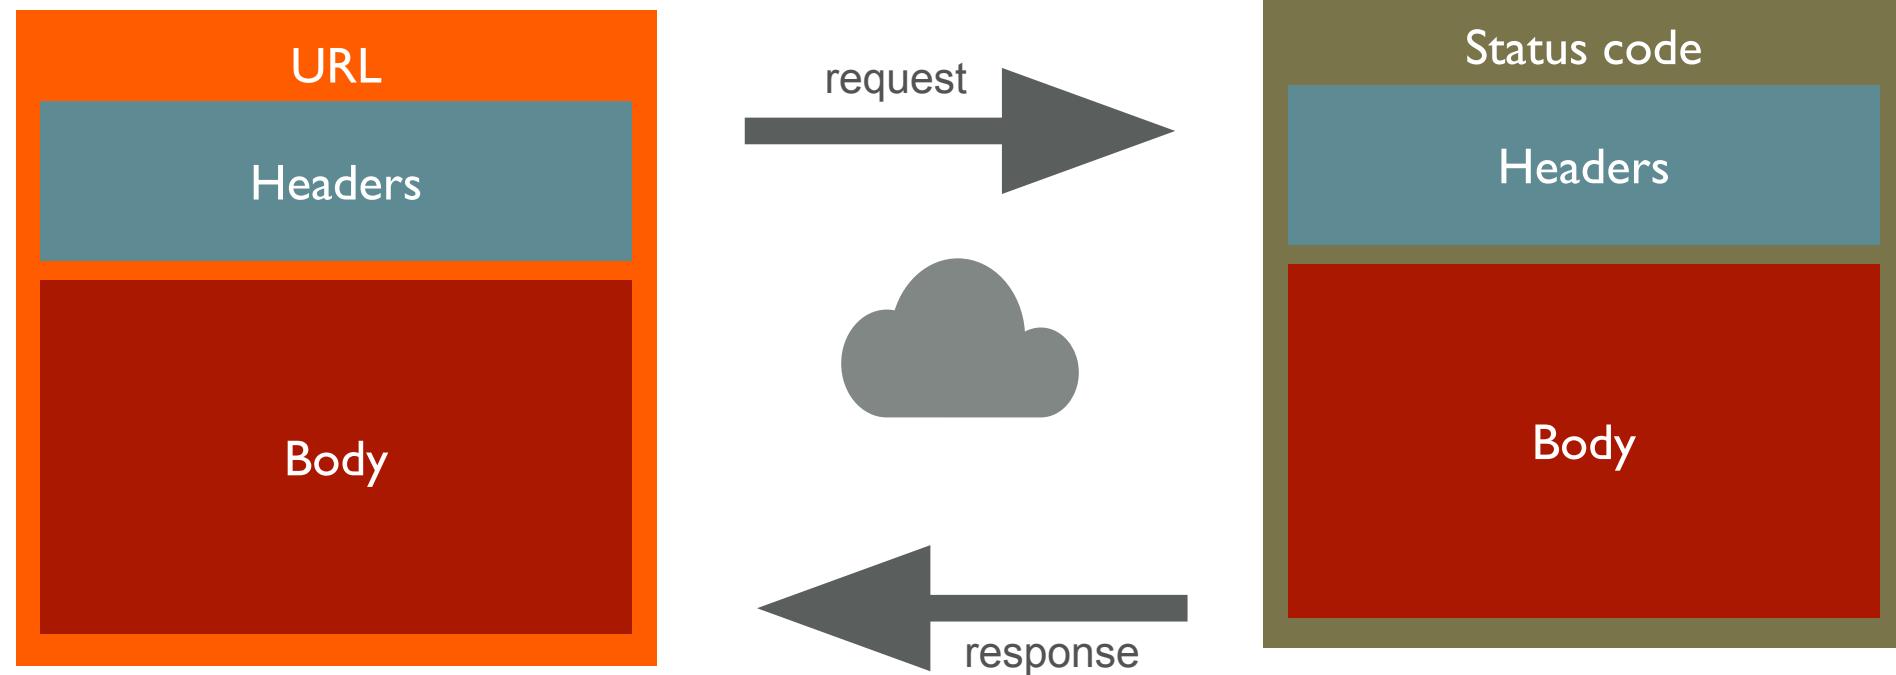

# If Your Client is an Application

GET, PUT, POST, DELETE

# HTTP

# REST: Nouns & Verbs

- **URIs** are the “nouns” of REST APIs:
  - Provide abstraction of resources and data.
  - e.g., what can be accessed:
    - [cs310.students.cs.ubc.ca/student/grades/](http://cs310.students.cs.ubc.ca/student/grades/)
    - [cs310.students.cs.ubc.ca/admin/grades/](http://cs310.students.cs.ubc.ca/admin/grades/)
- **Verbs** are the connection “methods”:
  - GET, PUT, POST, DEL (and PATCH, OPTIONS)
  - GET (retrieve), POST (create), PUT (update), DELETE (remove)
  - **Idempotency**: Will performing a VERB multiple times have the same result for server resources as performing it once?
    - Important in distributed systems.
    - **POST**: Is not idempotent; always makes new resources.
    - **Other Verbs**: Idempotent. Resources are consistent.

# Nouns: Resources

[www.piazza.com/courses/310/notes/145 << THIS IS THE URI.](http://www.piazza.com/courses/310/notes/145)  
[www.piazza.com/getCourses/ <<NO NO NO \(verb in URI\)](http://www.piazza.com/getCourses/)

- Resources are identified by “Uniform Resource Identifiers” (URIs)
- Examples:
  - Twitter resources include tweets, users, followers
  - Facebook resources include users, friends, posts
  - An email system’s resources might be contacts, and messages
- **URIs:** example:
  - [http://twitter.com/users/{id}/tweets/{id}/](http://twitter.com/users/{id}/tweets/{id})
  - <http://twitter.com/hashtags/{id}/tweets>
  - <http://twitter.com/hashtags/{id}/users/{id}/tweets>
  - <http://canafind.ca/locations/4/items/3>

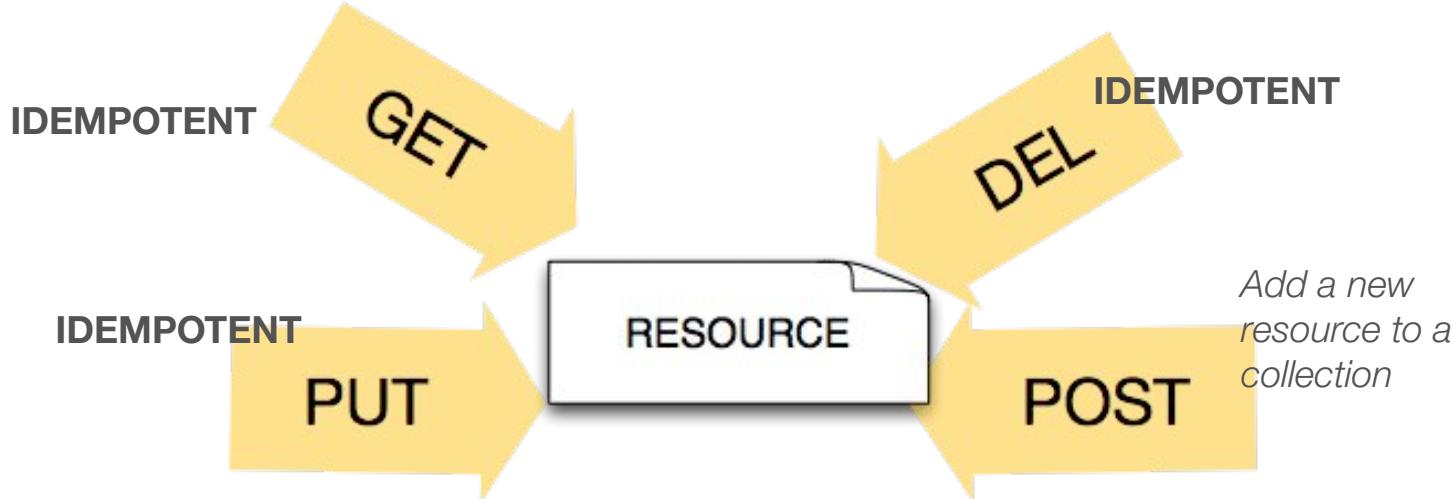

2 kinds of things:

- Items (individual)
- Collections (always plural)

CanaFind resources might be:

- **locations**
- **items**

# Verbs: GET/PUT/POST/DELETE

- Every resource must support (to some elegant extent) all four verbs.
- Examples:
  - A twitter client can get tweets, put/post tweets, delete tweets, etc.
  - An email client can get messages, get lists of users, post messages, delete messages, etc.

# REST Design Constraints

- Apply principled design process to commonly occurring challenges facing online applications.
- Needed to support networked sets of loosely coupled services.
- This led to several constraints, addressing provided properties:
  - Constraint: Replication needed to support caching.
  - Constraint: Uniform interface allowed simple mechanisms.
  - Constraint: Statelessness required for reliability.
  - Constraint: Connectedness supports discoverability.

# REST Design Principles

- **Resource-orientation:** Orienting designs around resources emphasizes a separation of concerns between a resource and the actions a system might perform on the resource. This commonly drives information hiding decisions in REST systems.
- **Uniform interface:** Having a consistent, predictable, and simple mechanism for marshalling requests and responses allows for clients and servers to independently evolve (for instance using different programming langs).
- **Statelessness:** All client requests need to contain all of the information needed to process a response. This is a fundamental decision that allows server resources to scale.
- **Self-descriptive messages:** Messages, especially responses, should contain information to help clients reason about how to process a response. This is most commonly used to enable follow-up actions for a resource. This often enables connectedness, where clients do not need to guess about an API.

POST

/repos/{owner}/{repo}/issues/{issue\_number}/comments

## Input

Name	Type	Description
body	string	<b>Required.</b> The contents of the comment.

```
{  
  "body": "Me too"  
}
```

**POST**

/repos/{owner}/{repo}/issues/{issue\_number}/comments

## Response

Status: 201 Created

Location: <https://api.github.com/repos/octocat>Hello-World/issues/comments/1>

POST

/repos/{owner}/{repo}/issues/{issue\_number}/comments

## Response

Status: 201 Created

Location: <https://api.github.com/repos/octocat>Hello-World/issues/comments/1>

```

```

# Design Flexibility

- URIs define resources, but there are many ways to pass additional data to the server:
  - PUT: /segments/{id}/starred
    - What *user* is applying the star?
  - DEL: /repos/../{repo}/pulls/../{review\_id}
    - Is the *user* performing the action permitted to delete this?
  - Potential options:
    - Headers, explicit parameters, request bodies.

# Developer Documentation

PUT

/segments/{id}/starred

## Parameters

id     The identifier of the segment to star.  
required Long, in path

---

starred     If true, star the segment; if false, unstar the  
required Boolean, in form segment.

# List push subscriptions

This request is used to retrieve the summary representations of the push subscriptions in place for the current application.

## Parameters

**client\_id:** **integer required**  
application's ID, obtained during registration

**client\_secret:** **string required**  
application's secret, obtained during registration

## Attributes

**id:** **integer**

**object\_type:** **string**  
object for which to get events, eg. 'activity'

**aspect\_type:** **string**  
aspect for which to get events, eg. 'create'

**callback\_url:** **string**

**created\_at:** **time string**

**updated\_at:** **time string**

## DEFINITION

GET [https://api.strava.com/api/v3/push\\_subscriptions](https://api.strava.com/api/v3/push_subscriptions)

## EXAMPLE REQUEST

```
$ curl -G https://api.strava.com/api/v3/push_subscriptions \
-d client_id=5 \
-d client_secret=7b2946535949ae70f015d696d8ac602830ece412
```

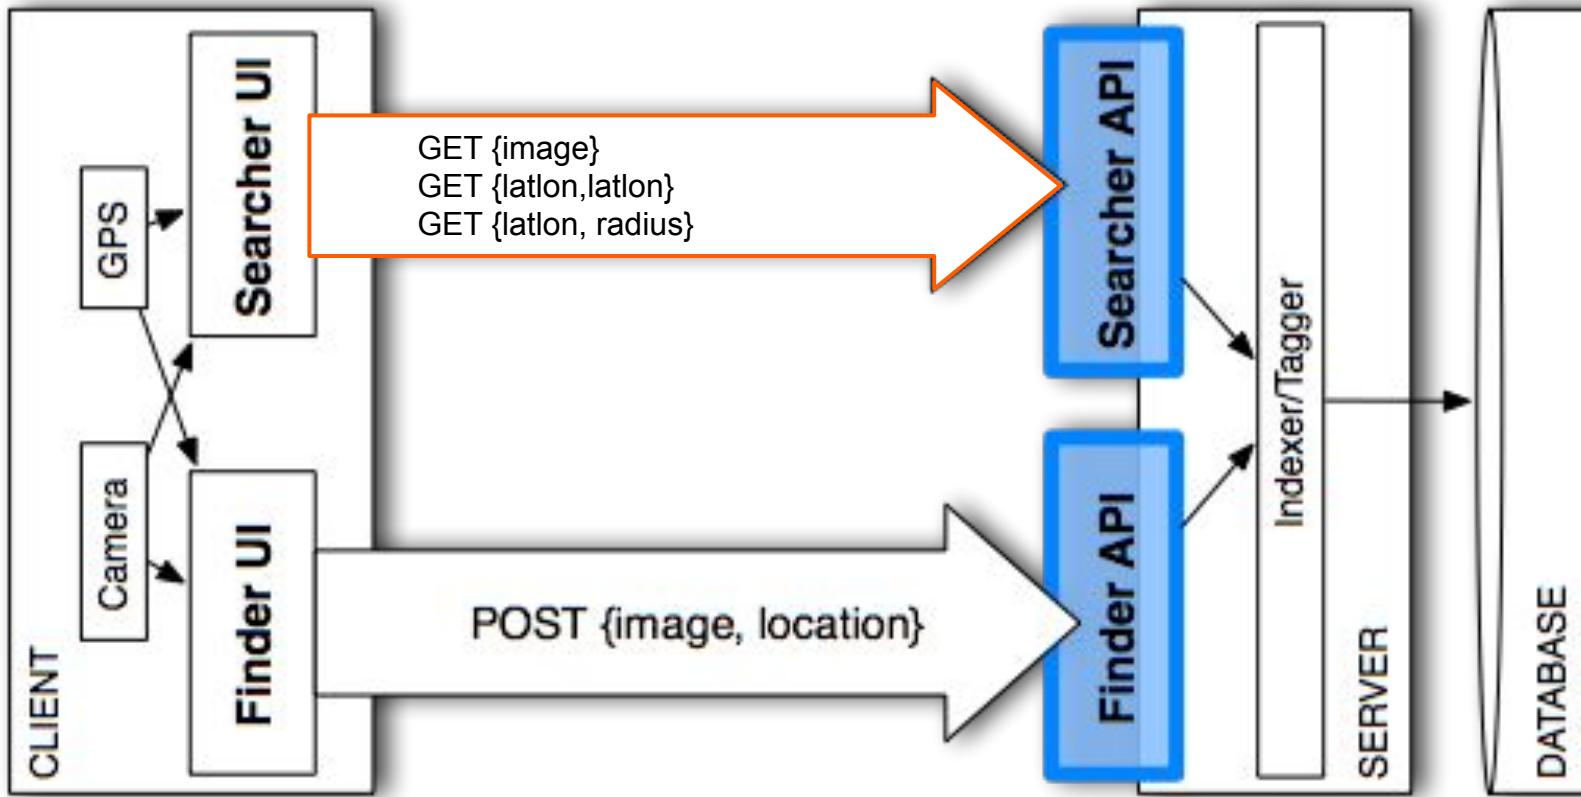

## EXAMPLE RESPONSES

[

```
{
  "id": 1,
  "object_type": "activity",
  "aspect_type": "create",
  "callback_url": "http://you.com/callback/",
  "created_at": "2015-04-29T18:11:09.400558047-07:00",
  "updated_at": "2015-04-29T18:11:09.400558047-07:00"
}
```

]

# RESTful CanaFind

# Enabling API Evolutionary Robustness

- Imagine the following response object:
  - `{name: 'cpsc autobot'}`
- But in the future you could imagine that you need to differentiate first and last names; one possible schema:
  - `{first: 'cpsc', last: 'autobot', name: 'cpsc autobot'}`
- REST resources as much as possible strive for backwards compatibility since frontend and backends are loosely coupled and may not be simultaneously updated.

# Versioning

- APIs are both assets and liabilities.
- Why would we want to version APIs?

# Versioning

- Path: GET /2017-01-01/customers/{id}/history
  - (Encode date of API version)
- Path: GET /2/customers/{id}/history
  - (Encode version in request)
- Path: GET /v2/customers/{id}/history
  - (Encode version in request)
- Query: GET /customers/{id}/history/?v=2
  - (Encode version in param)
- Specify the version in the header: APIVersion: 2

# RESTful Takeaways

- Resources are nouns, not verbs.
- All resources must elegantly handle:
  - GET/PUT/POST/DEL
  - Make sure GET/PUT/DEL are idempotent.
- All behavioural state must remain client-side.
- Clients should not have to remember the internal server structure — **send back links** in your responses to help clients discover the other resource location.

# DevOps

# Examinable skills

- Explain the rationale behind the DevOps movement.
- Identify key ideas and common practices in DevOps.
- Explain the value behind testing in production.
- Explain how A/B testing and canary releases work.
- Explain the role of automation and tools in DevOps.
- Understand the purpose Docker and Kubernetes fulfill in the DevOps environment.

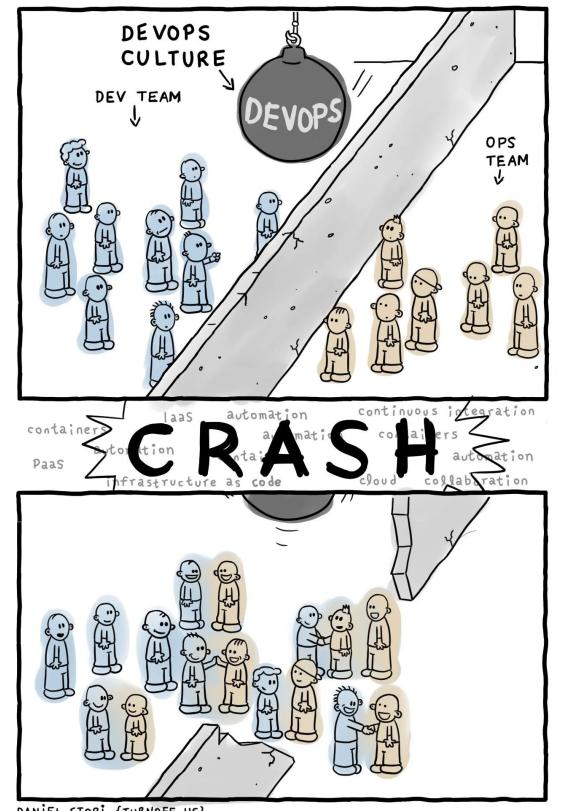

WORKED FINE IN  
DEV

OPS PROBLEM NOW

memegenerator.net

# How did we get here

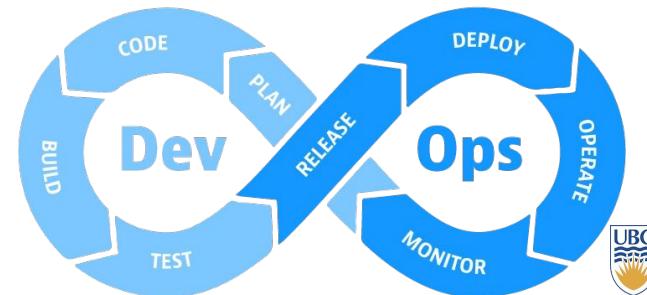

- Historically, the people who *develop the software*, and the people who *operate software* were not on the same teams.
- This divide has numerous downsides:
  - Poor communication.
  - Slow resolution of production issues.
  - Lengthened feedback loop.
  - Higher deployment cost/time.
- DevOps attempts to unify these teams.
- Automation crucial to enable almost all aspects of the modern DevOps toolbox.

# DevOps Key Goals

- Better coordinate between developers and operations (*collaborative*).
- Key goal: Reduce friction in bringing changes from development into production (*efficiency*).
- Consider the entire tool chain into production (*holistic*).
- Documentation and versioning of all dependencies and configurations ("configuration as code").
- Heavy *automation*, e.g., continuous delivery, monitoring.
- Small iterations, incremental and continuous releases.

Warning: Buzz word!

# Common release problems

## Examples:

- Missing dependencies.
- Different compiler versions or library versions.
- Different local utilities (e.g., unix grep vs mac grep).
- Database problems (config, auth, storage).
- OS differences.
- Too slow in real settings.
- Difficult to rollback changes.
- Source code from many different repositories.
- Obscure hardware? Cloud? Enough memory?

# DevOps divide

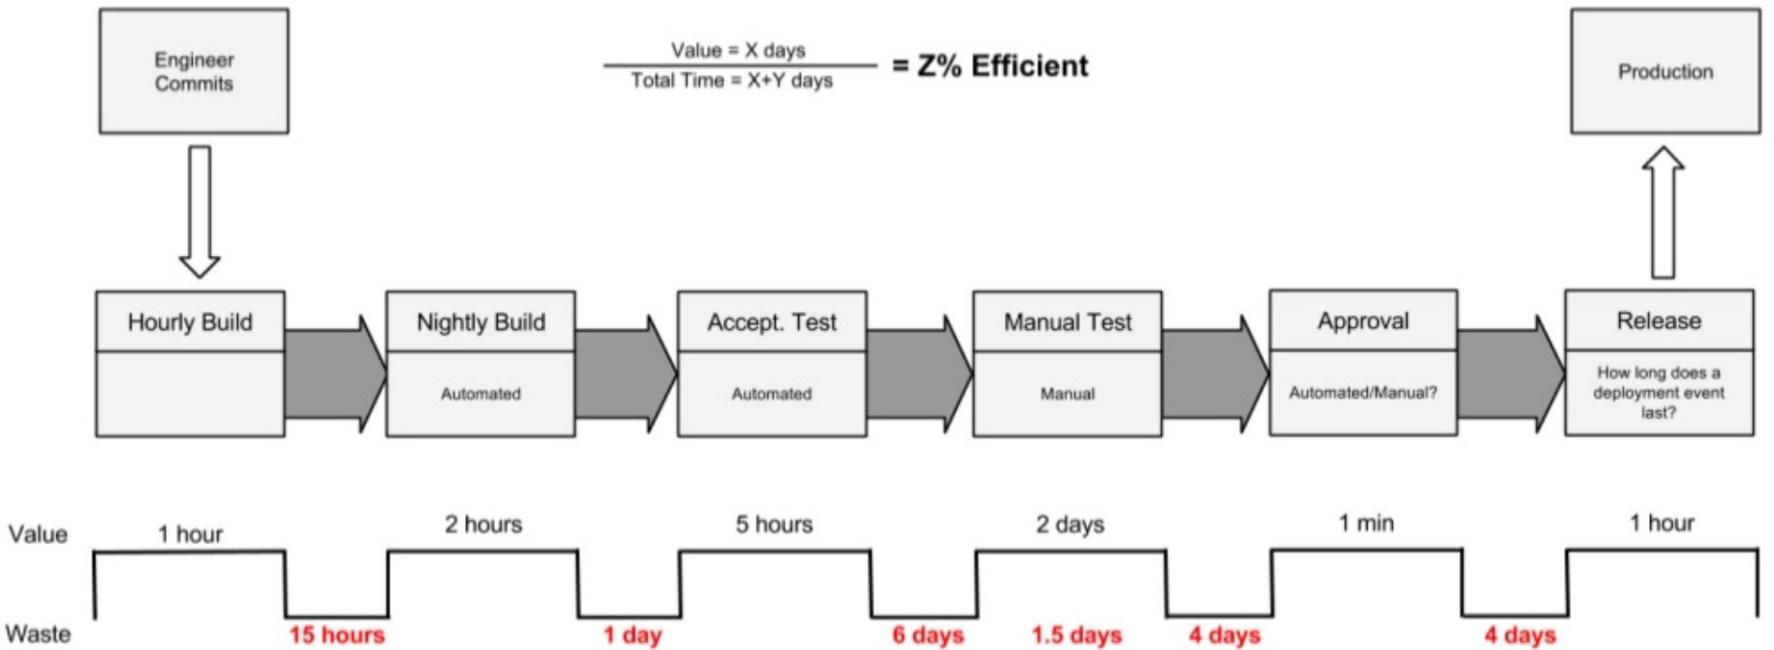

- Coding
- Testing
- Static analysis
- Code reviews
- Continuous integration
- Bug tracking
- Running local tests
- Local scalability experiments
- ...

- Allocating hardware resources
- Managing OS updates
- Monitoring performance
- Monitoring crashes
- Managing load spikes, ...
- Tuning DB performance
- Running distributed at scale
- Rolling back releases
- ...

# QA does not stop in dev

- Ensuring product builds correctly (e.g., reproducible builds).
- Ensuring scalability under real-world loads.
- Supporting environment constraints from real systems (hardware, software, OS).
- Efficiency with given infrastructure.
- Monitoring (server, database, Dr. Watson, etc).
- Bottlenecks, crash-prone components, ... (possibly thousands of crash reports per day/minute).

# Efficiency of release pipeline

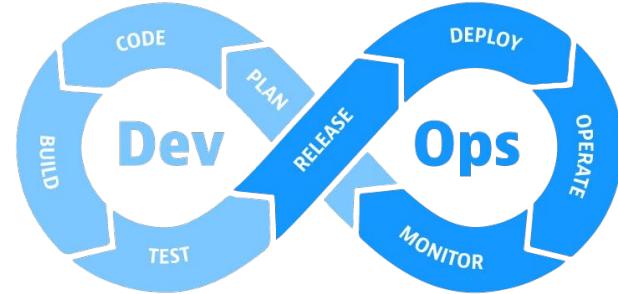

Netflix process: [<https://www.slideshare.net/jmcgarr/continuous-delivery-at-netflix-and-beyond>]

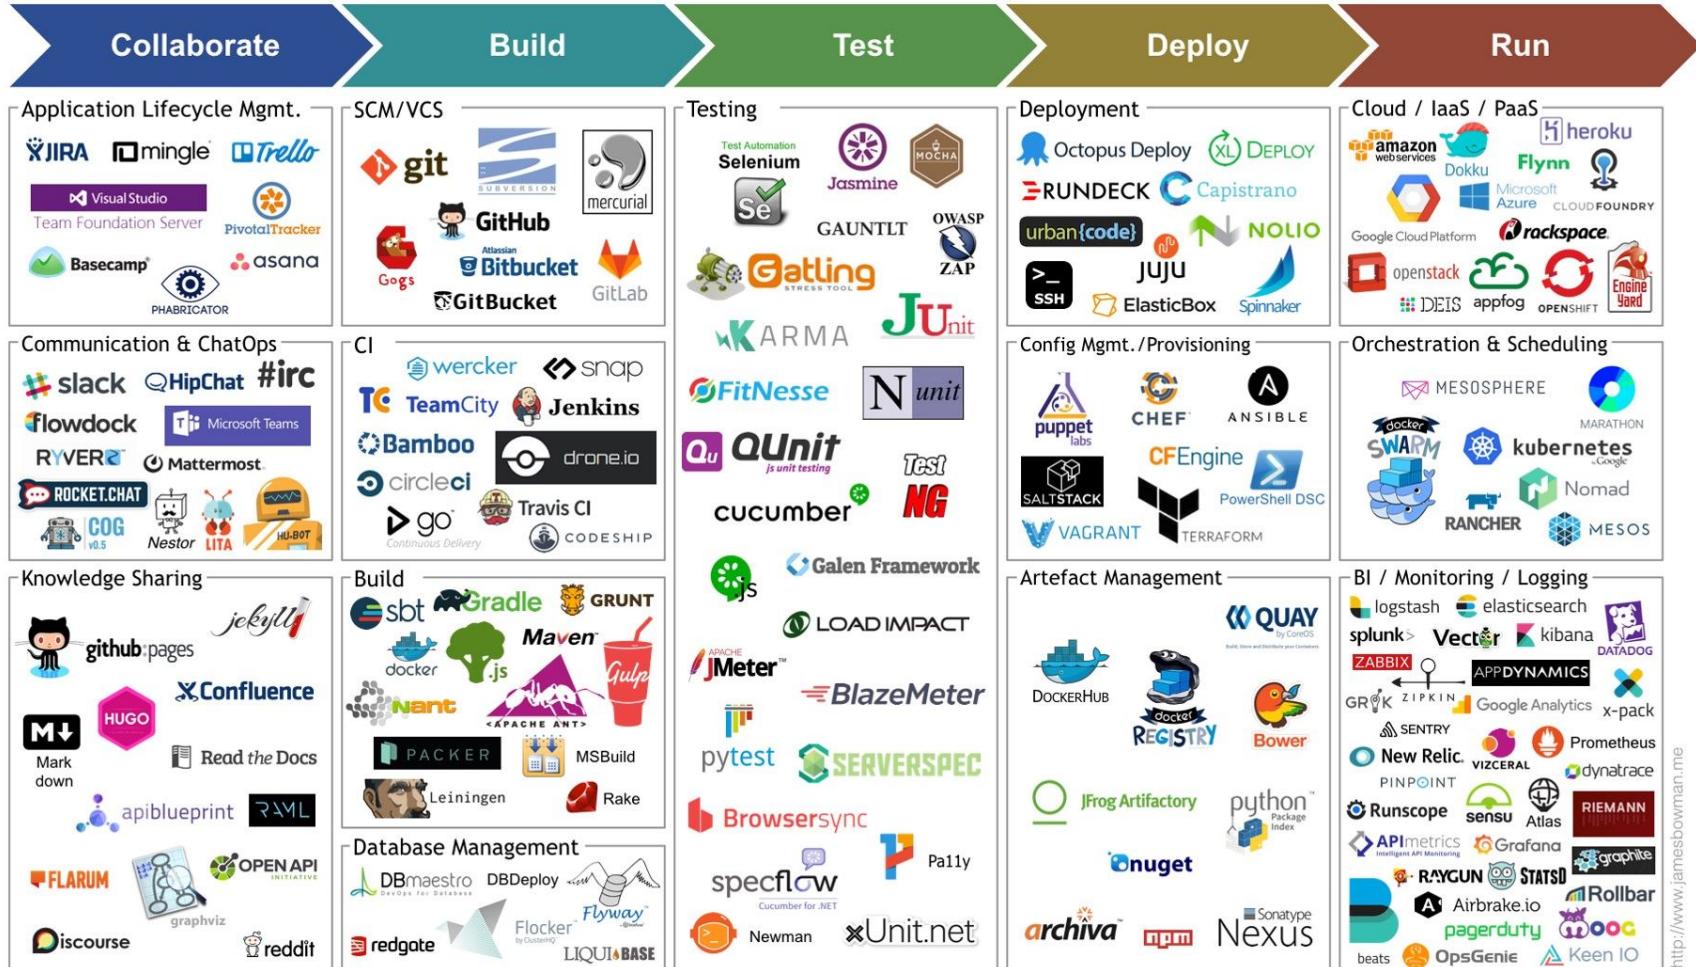

# Common DevOps practices

- All configurations in version control.
- Test and deploy in containers.
- Automated testing, testing, testing, ...
- Monitoring, orchestration, and automated actions in practice.
- Microservice architectures.
- Frequent releases.

# Heavy tooling/automation

<http://www.jamesbowman.me>

# Tooling/automation, examples

- Infrastructure as code: Ansible, **Terraform**, Puppet, Chef, **CloudFormation**.
- CI/CD: **Jenkins**, TeamCity, GitLab, Shippable, Bamboo, Azure DevOps, Bitbucket Pipelines.
- Test automation: Selenium, Cucumber, Apache JMeter.
- Containerization: **Docker**, Rocket, Unik.
- Orchestration: **Kubernetes**, Swarm, Mesos.
- Software deployment: Elastic Beanstalk, Octopus, Vamp.
- Measurement/Monitoring: Datadog, DynaTrace, Kibana, NewRelic, ServiceNow, **Prometheus**, **Grafana**.

- Lightweight virtualization.
- Sub-second boot time.
- Shareable virtual images with full setup & configuration.
- Used in development and deployment.
- Separate docker images for separate services (web server, business logic, database, ...).
- Weaker isolation than virtual machines: less secure.

# Configuration management, Infrastructure as Code (IaC)

- Scripts to change system configurations (configuration files, install packages, versions, ...); declarative vs imperative.
- Usually placed under version control.
- Cloud-native (e.g. AWS CloudFormation) vs. cloud-agnostic (e.g. Terraform).

```
EC2Instance:                                (AWS CloudFormation)
  Type: AWS::EC2::Instance
  Properties:
    InstanceType:
      Ref: InstanceType
    SecurityGroups:
      - Ref: InstanceSecurityGroup
    KeyName:
      Ref: KeyName
    ImageId:
      Fn::FindInMap:
        - AWSRegionArch2AMI
        - Ref: AWS::Region
        - Fn::FindInMap:
          - AWSInstanceType2Arch
          - Ref: InstanceType
          - Arch
```

```
provider "aws" {
  access_key = "${var.access_key}"
  secret_key = "${var.secret_key}"
  region = "us-east-1"
}

resource "aws_instance" "ec2_instance" {
  ami = "${var.ami_id}"
  count = "${var.number_of_instances}"
  subnet_id = "${var.subnet_id}"
  instance_type = "${var.instance_type}"
  key_name = "${var.ami_key_pair_name}"
}
```

# Kubernetes container orchestration

- Manages which container to deploy to which machine.
- Launches and kills containers depending on load.
- Manage updates and routing.
- Automated restart, replacement, replication, scaling.
- Kubernetes master controls many nodes.

# Monitoring

- Monitor server health.
- Monitor service health.
- Collect and analyze measures or log files.
- Dashboards and triggering automated decisions.
- Many tools, e.g., Grafana as dashboard, Prometheus for metrics, Loki + ElasticSearch for logs.
- Push and pull models.

# DevOps Measurement / Analytics

- When you service 1,000s of requests per second, understanding performance can be hard.
- **What would you measure?**

APP SERVER AVAILABILITY

**98.6152%**

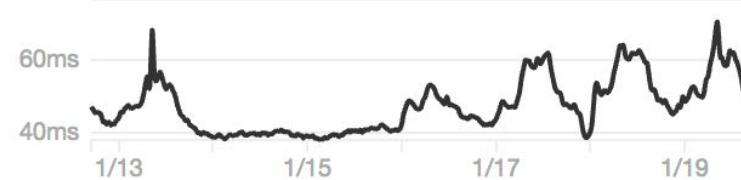

MEAN WEB RESPONSE TIME

**196ms**

MEAN API RESPONSE TIME

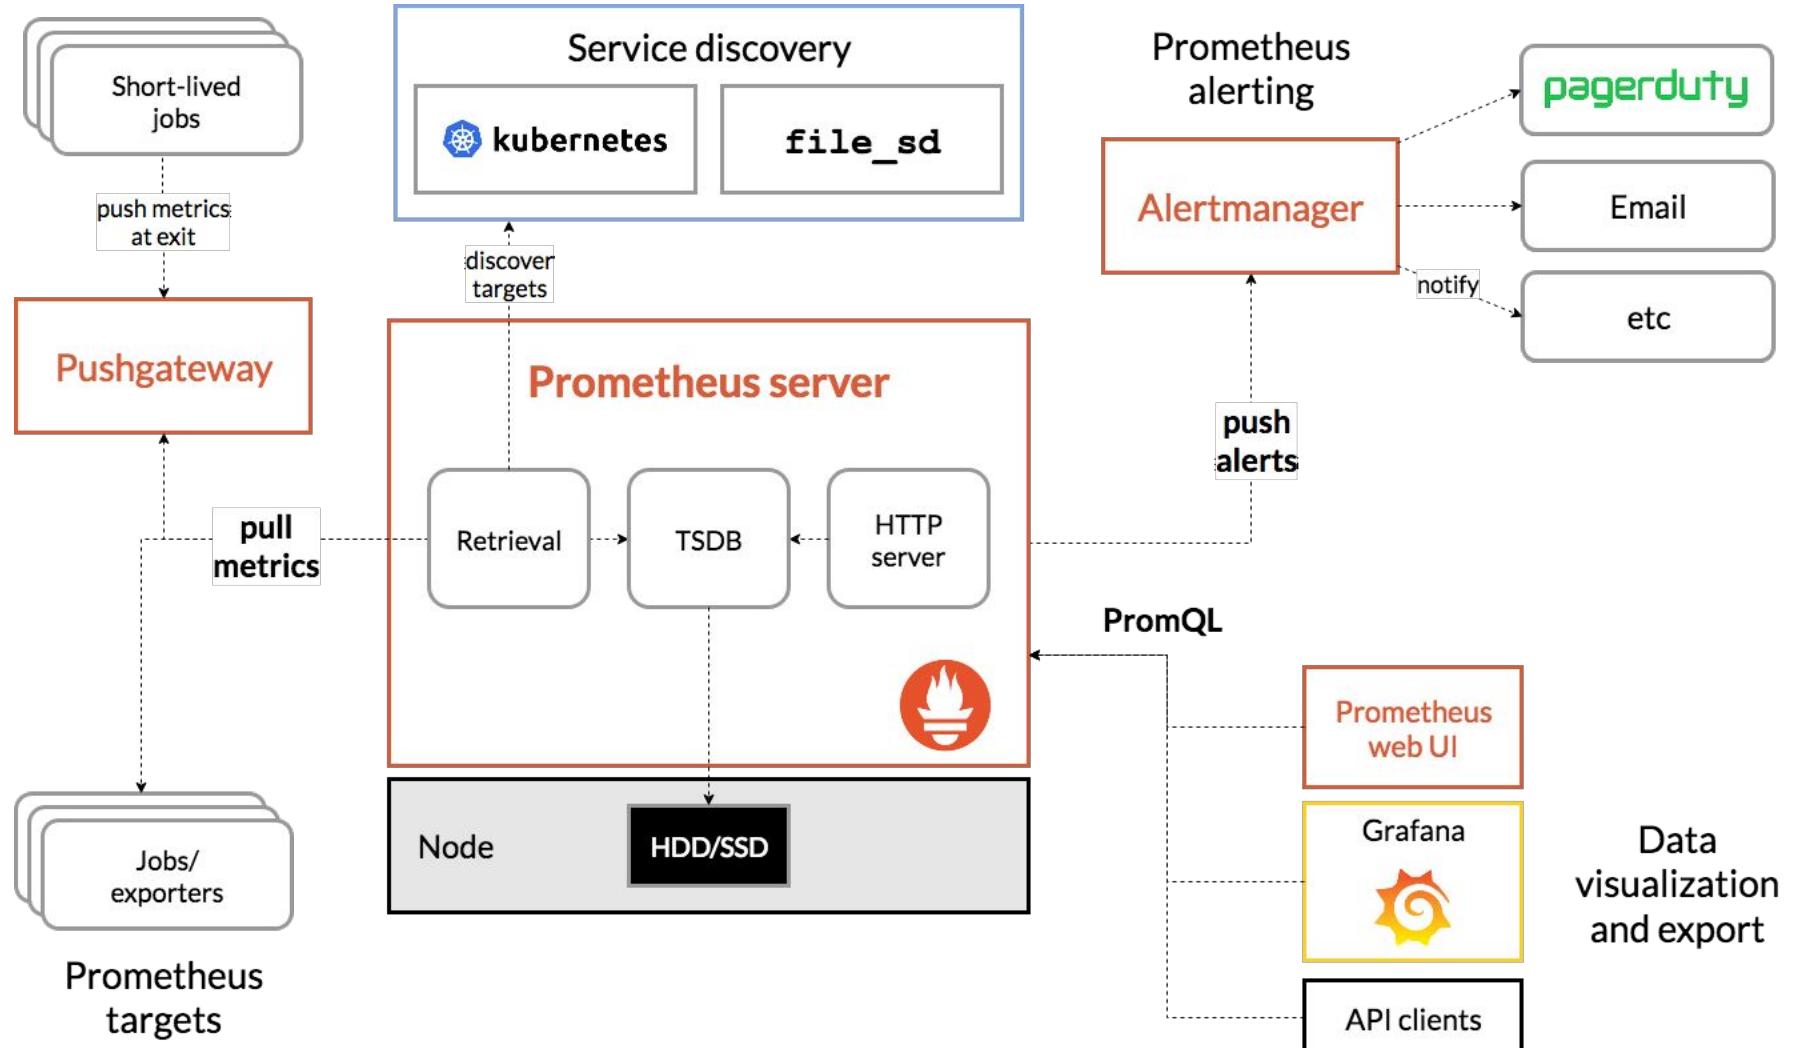

**47ms**

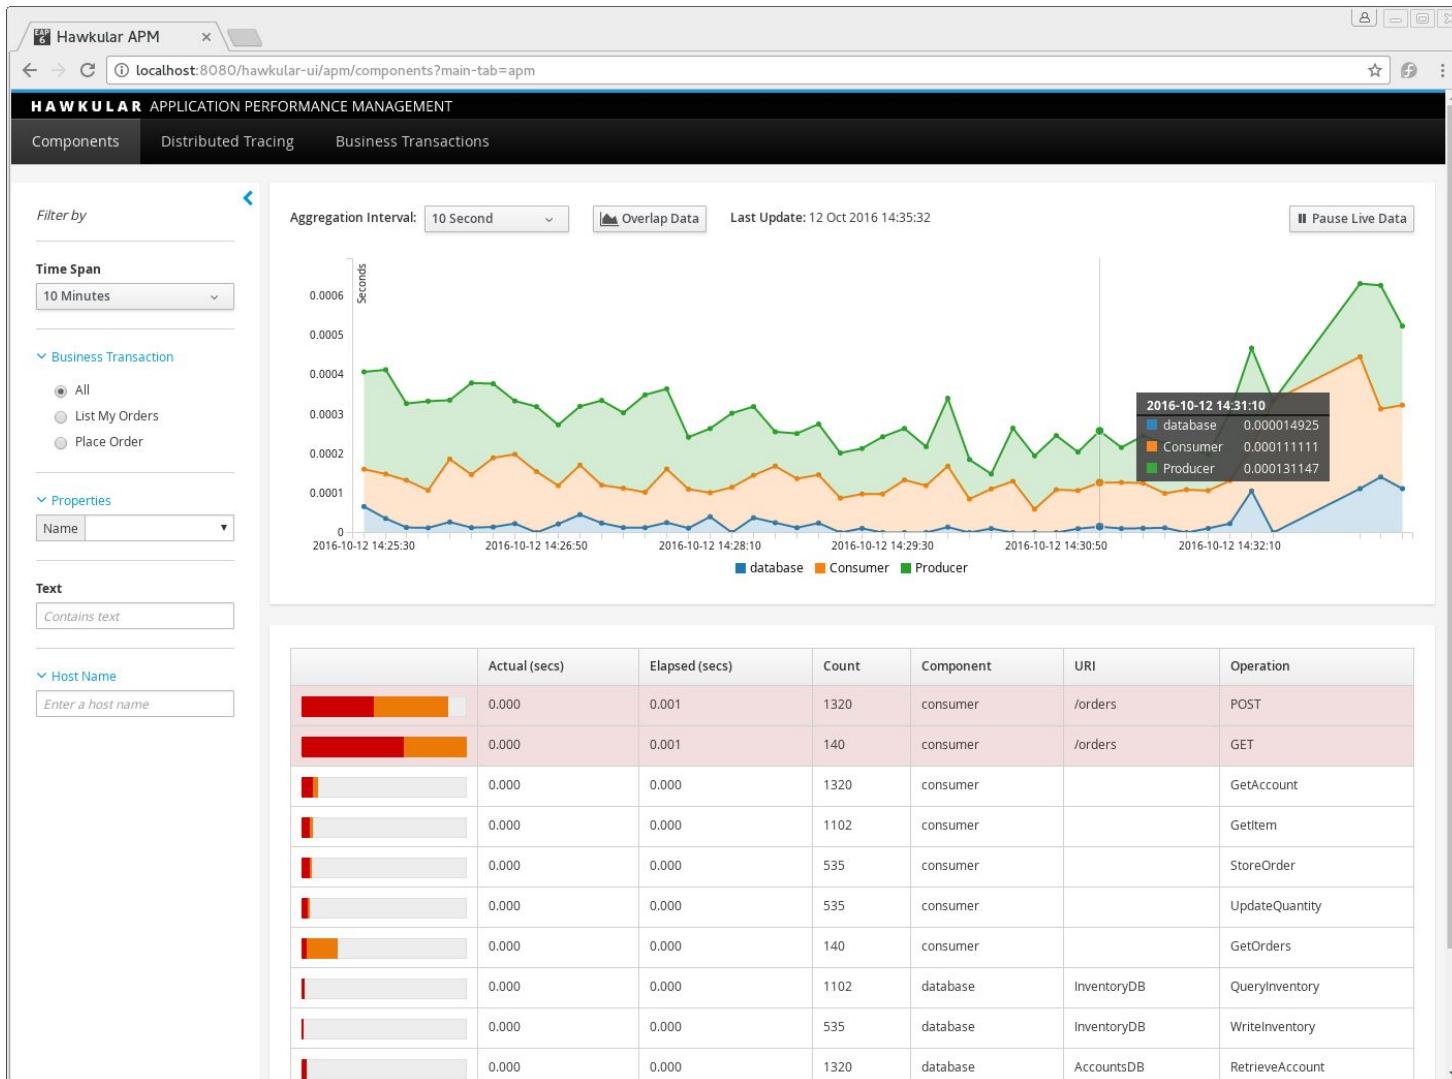

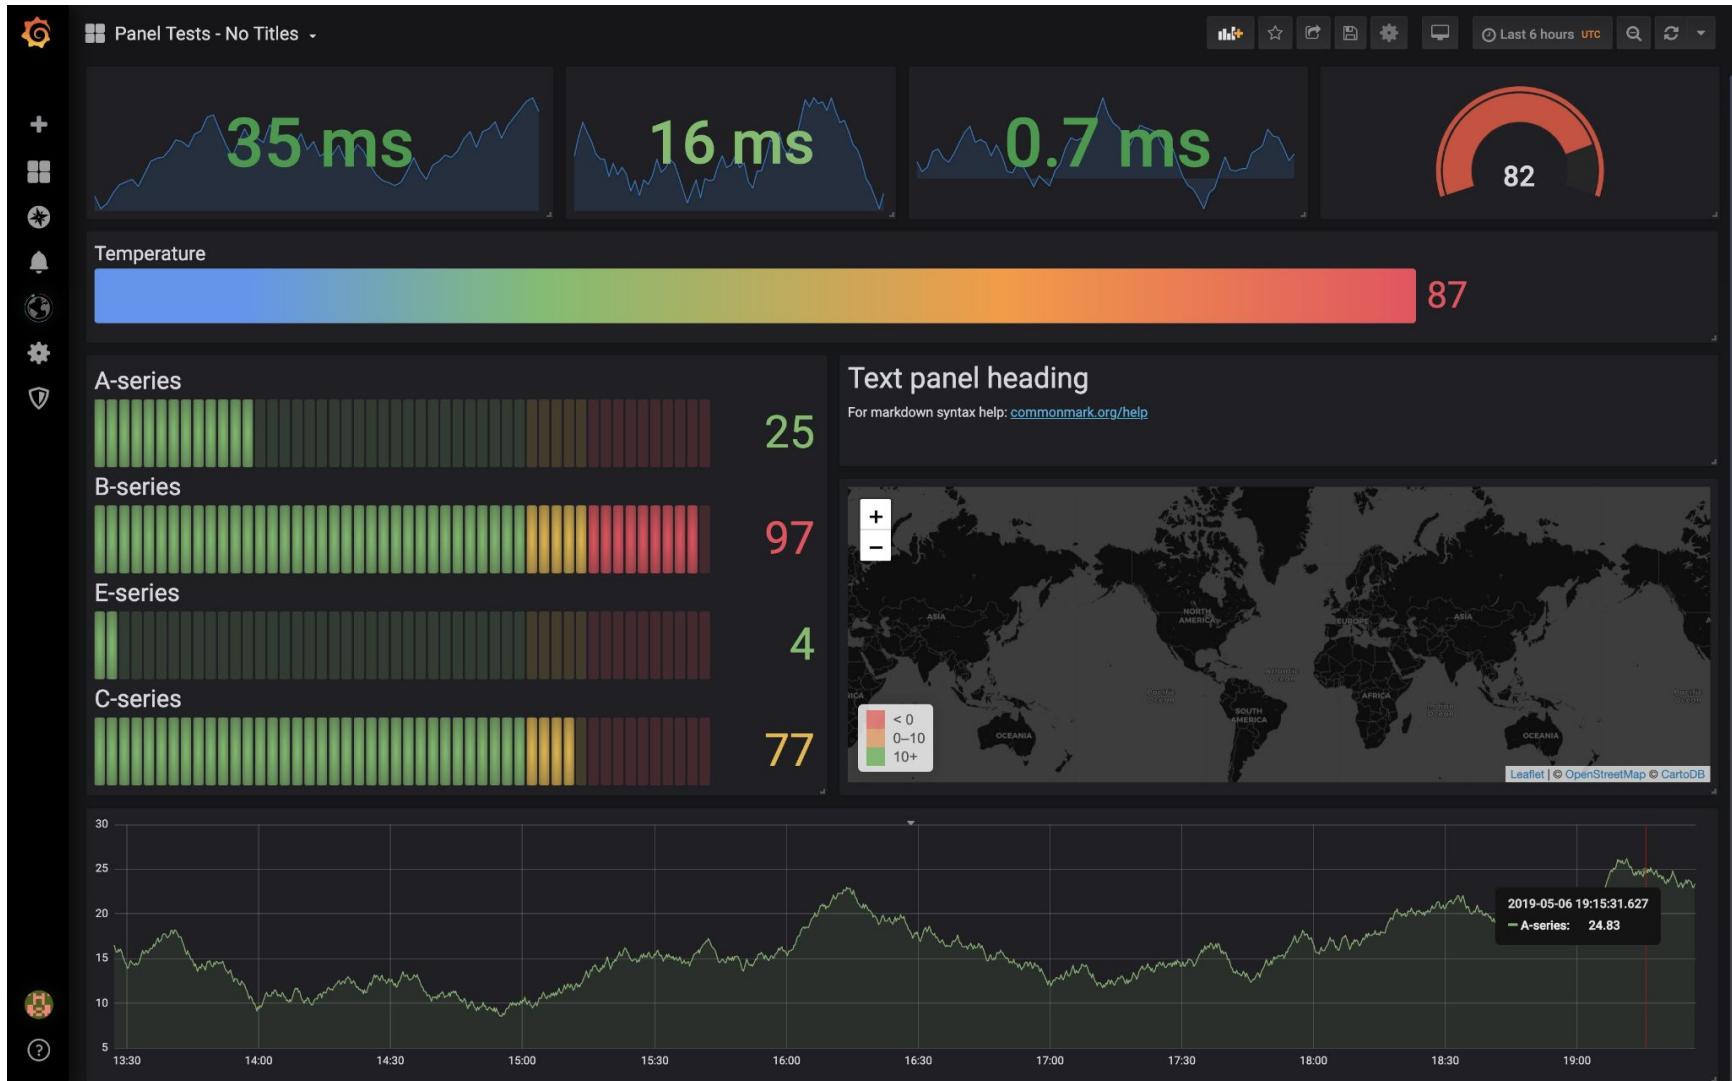

98TH PERC. WEB RESPONSE TIME

**761ms**

# Testing in production??

 Changelog

# Crash telemetry

# What if...?

- ... we had plenty of subjects for experiments.
  - ... we could randomly assign subjects to treatment and control group without them knowing.
  - ... we could analyze small individual changes and keep everything else constant.
- Ideal conditions for controlled experiments.

# A/B testing

Original: 2.3%

The original landing page for Groove features a large image of a smiling man in a plaid shirt. To his left, text reads: "SaaS & eCommerce Customer Support." Below it: "Managing customer support requests in Groove is so easy. Way better than trying to use Gmail or a more complicated help desk." A quote from "Griff, Customer Champion at Allocacoo" is present. At the bottom, a green button says "Learn More". Navigation links include "How it works", "What you get", "What it costs", and "How we're different". A bold statement at the bottom reads: "You'll be up and running in less than a minute."

Long Form: 4.3%

The long-form landing page for Groove has a similar layout but with more content. It includes a testimonial video featuring Allan, a customer success manager, discussing how Groove helps him grow his business. Text on the page emphasizes "personal support to every customer" and "assign support emails to the right people". A sidebar lists "WHAT YOU'LL DISCOVER ON THIS PAGE" with five bullet points: "Three reasons growing teams choose Groove", "How Groove makes your whole team more productive", "Delivering a personal support experience every time", "Take a screenshot tour", and "A personal note from our CEO". Social media icons for BuySellAds, METACRAFTER, and StatusPage.io are at the bottom.

# Experiment size

- With enough subjects (users), we can run many many experiments.
- Even very small experiments become feasible.

# A/B testing

- **Implement alternative versions** of the system:
  - Using feature flags (decisions in implementation)
  - Separate deployments (decision in router/load balancer).
- **Map users** to treatment group:
  - Randomly from distribution.
  - Static user - group mapping.
  - Online service (e.g., launchdarkly, split).
- **Monitor outcomes** per group:
  - Telemetry, sales, time on site, server load, crash rate.

# Feature flags

- Boolean options.
- Good practices; features are:
  - Tracked explicitly and documented.
  - Localized and independent.
- External mapping of flags to customers:
  - Who should see what configuration.
    - e.g., the same 1% of users sees one\_click\_checkout, or 50% of beta-users and 90% of developers and 0.1% of all users.

```
if (features.enabled(userId, "one_click_checkout")) {  
    // new one click checkout function  
} else {  
    // old checkout functionality  
}  
  
def isEnabled(user): Boolean = (hash(user.id) % 100) < 10
```

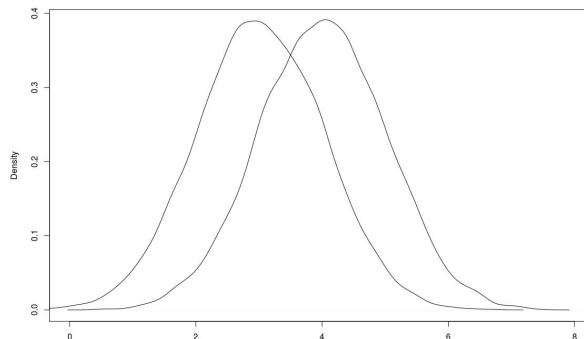

# Comparing outcomes

## Group A

- base game
- 2158 Users
- average 18:13 min time on site

## Group B

- game with extra god cards
- 2020 Users
- average 20:24 min time on site

# The Morality Of A/B Testing

Josh Constine @joshconstine / 11:50 PM EDT • June 29, 2014

 Comment

We don't use the "real" Facebook. Or Twitter. Or Google, Yahoo, or LinkedIn. We are almost all part of experiments they quietly run to see if different versions with little changes make us use more, visit more, click more, or buy more. By signing up for these services, we technically give consent to be treated like guinea pigs.

But this weekend, Facebook stirred up [controversy](#) because one of its data science researchers published the results of an experiment on 689,003 users to see if showing them more positive or negative sentiment posts in the News Feed would affect their happiness levels as deduced by what they posted. The impact of this experiment on manipulating emotions was tiny, but it

# Canary releases

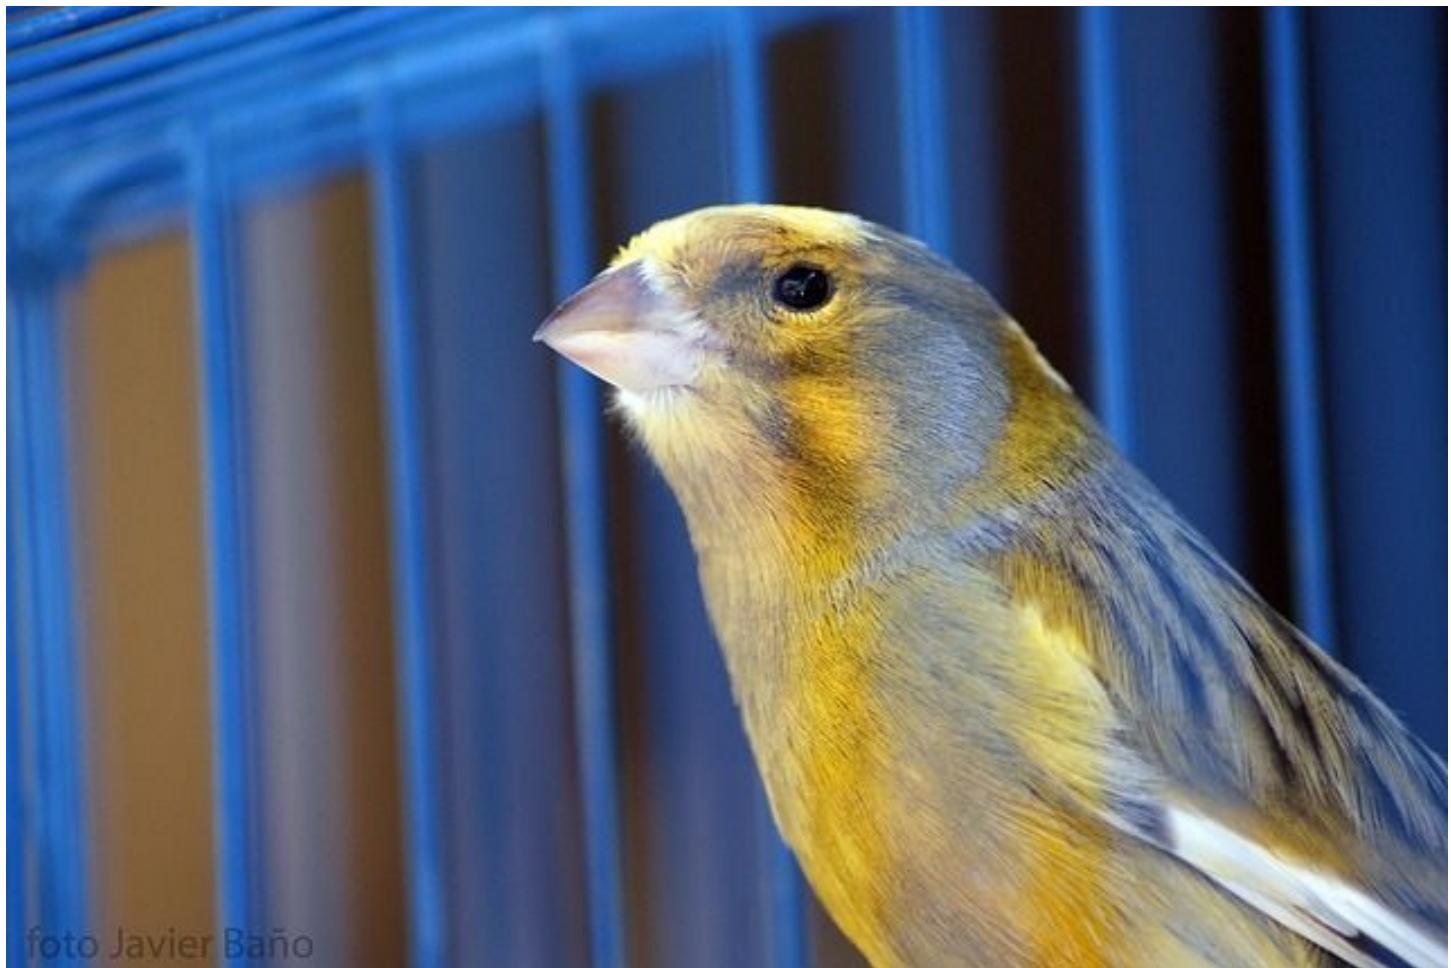

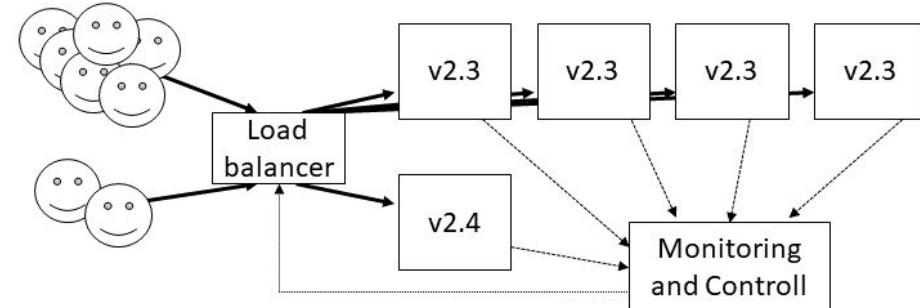

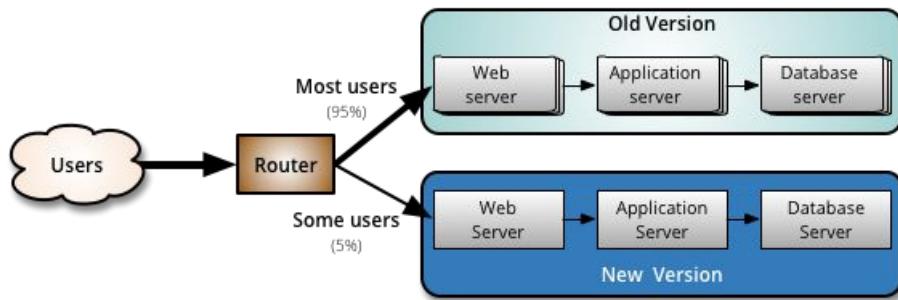

foto Javier Baño

# Canary releases

- Testing releases in production.
- **Incrementally deploy** a new release to users, not all at once.
- **Monitor difference in outcomes** (e.g., crash rates, performance, user engagement).
- **Automatically roll back** bad releases.
- Simple version of A/B testing.
- Telemetry essential.

# Chaos Experiments

“A chaos experiment in production allows you to measure a system's traffic, patterns of use, resource utilization, and practical application. This information can help build resilience within the system and improve cyber defenses.”

# Chaos Experiments

**Chaos Monkey**  
Randomly disables production instances

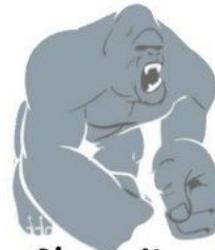

**Chaos Gorilla**

Outage of entire Amazon Availability Zone

**Janitor Monkey**  
Identifies and disposes unused resources

**Chaos Kong**  
Drops a full AWS Region

**Conformity Monkey**  
Shuts down instances not adhering to best-practices

@geosley

**Security Monkey**  
Finds security violations and vulnerability

**Doctor Monkey**  
Taps into health checks and fixes unhealthy resources

**Latency Monkey**  
Simulate degradation or outages in a network

# The complexity of real DevOps pipelines

- Incremental rollout, re-configuring routers.
- Canary testing.
- Automatic change rollback.

Further readings: Chunqiang et al. *Holistic configuration management at Facebook*. In Proceedings of the 25th Symposium on Operating Systems Principles. 2015.

# DevOps summary

- Code only has value if it can be used. Most modern systems are deployed rather than physically shipped.
- Increasing automation of tests and deployments.
- Containers and configuration management tools help with automation, deployment, and rollbacks.
- Monitoring becomes crucial.
- Enables many opportunities for testing in production: A/B testing, canary releases, feature flags as mechanism.
